[4577] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM319 gene, herein designated GAM GENE, on one or more GAM319 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4578] It is yet further appreciated that specific functions, and accordingly utilities, of GAM319 correlate with, and may be deduced from, the identity of the target genes which GAM319 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4579] Nucleotide sequences of the GAM319 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM319 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM319 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM319 are further described hereinbelow with reference to Table Table1.

[4580] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM319 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4581]

[4582] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 320 (GAM320) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4583] GAM320 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM320 was detected is described hereinabove with reference to Figs. 2-8.

[4584] GAM320 gene, herein designated GAM GENE, and

GAM320 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4585] GAM320 gene, herein designated GAM GENE, encodes a GAM320 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM320 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM320 precursor RNA is designated SEQ ID:4873, and is provided hereinbelow with reference to the sequence listing part.

[4586] GAM320 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM320 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4587] An enzyme complex designated DICER COMPLEX, dices the GAM320 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM320 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM320 RNA is designated SEQ ID:4874, and is provided hereinbelow with reference to the sequence listing part.

[4588] GAM320 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM320 target RNA, herein designated GAM TARGET RNA. GAM320 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4589] GAM320 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM320 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM320 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM320 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM320 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4590] The complementary binding of GAM320 RNA, herein designated GAM RNA, to target binding sites on GAM320 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM320 target RNA, herein designated GAM TARGET RNA, into GAM320 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4591] It is appreciated that GAM320 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM320 target genes. The mRNA of each one of this plurality of GAM320 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM320 RNA, herein designated GAM RNA, and which when bound by GAM320 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM320 target proteins.

[4592] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM320 gene, herein designated GAM GENE, on one or more GAM320 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4593] It is yet further appreciated that specific functions, and accordingly utilities, of GAM320 correlate with, and may be deduced from, the identity of the target genes which GAM320 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4594] Nucleotide sequences of the GAM320 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM320 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM320 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM320 are further described hereinbelow with reference to Table Table1.

[4595] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM320 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4596]

[4597] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 321 (GAM321) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4598] GAM321 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM321 was detected is described hereinabove with reference to Figs. 2-8.

[4599] GAM321 gene, herein designated GAM GENE, and GAM321 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4600] GAM321 gene, herein designated GAM GENE, encodes a GAM321 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM321 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM321 precursor RNA is designated SEQ ID:4918, and is provided hereinbelow with reference to the sequence listing part.

[4601] GAM321 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM321 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4602] An enzyme complex designated DICER COMPLEX, dices the GAM321 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM321 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM321 RNA is designated SEQ ID:4919, and is provided hereinbelow with reference to the sequence listing part.

[4603] GAM321 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM321 target RNA, herein designated GAM TARGET RNA. GAM321 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4604] GAM321 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM321 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM321 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM321 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM321 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4605] The complementary binding of GAM321 RNA, herein designated GAM RNA, to target binding sites on GAM321 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM321 target RNA, herein designated GAM TARGET RNA, into GAM321 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4606] It is appreciated that GAM321 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM321 target genes. The mRNA of each one of this plurality of GAM321 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM321 RNA, herein designated GAM RNA, and which when bound by GAM321 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM321 target proteins.

[4607] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM321 gene, herein designated GAM GENE, on one or more GAM321 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4608] It is yet further appreciated that specific functions, and accordingly utilities, of GAM321 correlate with, and may be deduced from, the identity of the target genes which GAM321 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4609] Nucleotide sequences of the GAM321 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM321 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM321 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM321 are further described hereinbelow with reference to Table Table1.

[4610] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM321 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4611]

[4612] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 322 (GAM322) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4613] GAM322 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM322 was detected is described hereinabove with reference to Figs. 2-8.

[4614] GAM322 gene, herein designated GAM GENE, and GAM322 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4615] GAM322 gene, herein designated GAM GENE, encodes a GAM322 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM322 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM322 precursor RNA is designated SEQ ID:4923, and is provided hereinbelow with reference to the sequence listing part.

[4616] GAM322 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM322 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4617] An enzyme complex designated DICER COMPLEX, dices the GAM322 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM322 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM322 RNA is designated SEQ ID:4924, and is provided hereinbelow with reference to the sequence listing part.

[4618] GAM322 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM322 target RNA, herein designated GAM TARGET RNA. GAM322 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4619] GAM322 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM322 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM322 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM322 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM322 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4620] The complementary binding of GAM322 RNA, herein designated GAM RNA, to target binding sites on GAM322 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM322 target RNA, herein designated GAM TARGET RNA, into GAM322 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4621] It is appreciated that GAM322 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM322 target genes. The mRNA of each one of this plurality of GAM322 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM322 RNA,

herein designated GAM RNA, and which when bound by GAM322 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM322 target proteins.

[4622] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM322 gene, herein designated GAM GENE, on one or more GAM322 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4623] It is yet further appreciated that specific functions, and accordingly utilities, of GAM322 correlate with, and may be deduced from, the identity of the target genes which

GAM322 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4624] Nucleotide sequences of the GAM322 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM322 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM322 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM322 are further described hereinbelow with reference to Table Table1.

[4625] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM322 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4626]

[4627] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 323 (GAM323) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4628] GAM323 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM323 was detected is described hereinabove with reference to Figs. 2-8.

[4629] GAM323 gene, herein designated GAM GENE, and GAM323 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4630] GAM323 gene, herein designated GAM GENE, encodes a GAM323 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM323 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM323 precursor RNA is designated SEQ ID:4942, and is provided hereinbelow with reference to the sequence listing part.

[4631] GAM323 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM323 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[4632] An enzyme complex designated DICER COMPLEX, dices the GAM323 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM323 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 25%) nucleotide sequence of GAM323 RNA is designated SEQ ID:4943, and is provided hereinbelow with reference to the sequence listing part.

[4633] GAM323 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM323 target RNA, herein designated GAM TARGET RNA.
GAM323 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4634] GAM323 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM323 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM323 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM323 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM323 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4635] The complementary binding of GAM323 RNA, herein designated GAM RNA, to target binding sites on GAM323 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM323 target RNA, herein desig-

nated GAM TARGET RNA, into GAM323 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4636] It is appreciated that GAM323 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM323 target genes. The mRNA of each one of this plurality of GAM323 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM323 RNA, herein designated GAM RNA, and which when bound by GAM323 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM323 target proteins.

[4637] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM323 gene, herein designated GAM GENE, on one or more GAM323 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4638] It is yet further appreciated that specific functions, and accordingly utilities, of GAM323 correlate with, and may be deduced from, the identity of the target genes which GAM323 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4639] Nucleotide sequences of the GAM323 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM323 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM323 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM323 are further described hereinbelow with reference to Table Table1.

[4640] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM323 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[4641]

[4642] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 324 (GAM324) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4643] GAM324 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM324 was detected is described hereinabove with reference to Figs. 2-8.

[4644] GAM324 gene, herein designated GAM GENE, and GAM324 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4645] GAM324 gene, herein designated GAM GENE, encodes a GAM324 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM324 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM324 precursor RNA is designated SEQ ID:4958, and is provided hereinbelow with ref-

erence to the sequence listing part.

[4646] GAM324 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM324 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4647] An enzyme complex designated DICER COMPLEX, dices the GAM324 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM324 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM324 RNA is designated SEQ ID:4959, and is provided hereinbelow with reference to the sequence listing part.

[4648] GAM324 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM324 target RNA, herein designated GAM TARGET RNA.

GAM324 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4649] GAM324 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM324 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM324 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM324 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM324 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4650] The complementary binding of GAM324 RNA, herein designated GAM RNA, to target binding sites on GAM324 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM324 target RNA, herein designated GAM TARGET RNA, into GAM324 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4651] It is appreciated that GAM324 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM324 target genes. The mRNA of each one of this plurality of GAM324 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM324 RNA, herein designated GAM RNA, and which when bound by GAM324 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM324 target proteins.

[4652] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM324 gene, herein designated GAM GENE, on one or more GAM324 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4653] It is yet further appreciated that specific functions, and accordingly utilities, of GAM324 correlate with, and may be deduced from, the identity of the target genes which GAM324 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4654] Nucleotide sequences of the GAM324 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM324 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM324 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM324 are further described hereinbelow with reference to Table Table1.

[4655] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM324 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4656]

[4657] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 325 (GAM325) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4658] GAM325 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM325 was detected is described hereinabove with reference to Figs. 2-8.

[4659] GAM325 gene, herein designated GAM GENE, and GAM325 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[4660] GAM325 gene, herein designated GAM GENE, encodes a GAM325 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM325 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM325 precursor RNA is designated SEQ ID:4970, and is provided hereinbelow with reference to the sequence listing part.

[4661] GAM325 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM325 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4662] An enzyme complex designated DICER COMPLEX, dices the GAM325 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM325 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM325 RNA is designated SEQ ID:4971, and is provided hereinbelow with reference to the sequence listing part.

[4663] GAM325 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM325 target RNA, herein designated GAM TARGET RNA. GAM325 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4664] GAM325 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM325 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM325 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM325 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM325 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4665] The complementary binding of GAM325 RNA, herein designated GAM RNA, to target binding sites on GAM325 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM325 target RNA, herein designated GAM TARGET RNA, into GAM325 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4666] It is appreciated that GAM325 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM325 target genes. The mRNA of each one of this plurality of GAM325 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM325 RNA, herein designated GAM RNA, and which when bound by GAM325 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM325 target proteins.

[4667] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM325 gene, herein designated GAM GENE, on one or more GAM325 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[4668] It is yet further appreciated that specific functions, and accordingly utilities, of GAM325 correlate with, and may be deduced from, the identity of the target genes which GAM325 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4669] Nucleotide sequences of the GAM325 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM325 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM325 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM325 are further described hereinbelow with reference to Table Table1.

[4670] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM325 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4671]

[4672] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

326 (GAM326) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4673] GAM326 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM326 was detected is described hereinabove with reference to Figs. 2-8.

[4674] GAM326 gene, herein designated GAM GENE, and GAM326 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4675] GAM326 gene, herein designated GAM GENE, encodes a GAM326 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM326 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM326 precursor RNA is designated SEQ ID:4974, and is provided hereinbelow with reference to the sequence listing part.

[4676] GAM326 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM326 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4677] An enzyme complex designated DICER COMPLEX, dices the GAM326 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM326 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 48%) nucleotide sequence of GAM326 RNA is designated SEQ ID:4975, and is provided hereinbelow with reference to the sequence listing part.

[4678] GAM326 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM326 target RNA, herein designated GAM TARGET RNA. GAM326 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4679] GAM326 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM326 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM326 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM326 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM326 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4680] The complementary binding of GAM326 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM326 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM326 target RNA, herein designated GAM TARGET RNA, into GAM326 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4681] It is appreciated that GAM326 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM326 target genes. The mRNA of each one of this plurality of GAM326 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM326 RNA, herein designated GAM RNA, and which when bound by GAM326 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM326 target proteins.

[4682] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM326 gene, herein designated GAM GENE, on one or more GAM326 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4683] It is yet further appreciated that specific functions, and accordingly utilities, of GAM326 correlate with, and may be deduced from, the identity of the target genes which GAM326 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4684] Nucleotide sequences of the GAM326 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM326 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM326 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM326 are further described hereinbelow with reference to Table Table1.

[4685] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM326 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4686]

[4687] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 327 (GAM327) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4688] GAM327 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM327 was detected is described hereinabove with reference to Figs. 2-8.

[4689] GAM327 gene, herein designated GAM GENE, and GAM327 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4690] GAM327 gene, herein designated GAM GENE, encodes a GAM327 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM327 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM327 precursor RNA is designated SEQ ID:4979, and is provided hereinbelow with reference to the sequence listing part.

[4691] GAM327 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM327 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4692] An enzyme complex designated DICER COMPLEX, dices the GAM327 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM327 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 51%) nucleotide sequence of GAM327 RNA is designated SEQ ID:4980, and is provided hereinbelow with reference to the sequence listing part.

[4693] GAM327 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM327 target RNA, herein designated GAM TARGET RNA. GAM327 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4694] GAM327 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM327 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM327 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM327 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM327 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4695] The complementary binding of GAM327 RNA, herein designated GAM RNA, to target binding sites on GAM327 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM327 target RNA, herein designated GAM TARGET RNA, into GAM327 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4696] It is appreciated that GAM327 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM327 target genes. The mRNA of each one of this plurality of GAM327 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM327 RNA, herein designated GAM RNA, and which when bound by

GAM327 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM327 target proteins.

[4697] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM327 gene, herein designated GAM GENE, on one or more GAM327 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4698] It is yet further appreciated that specific functions, and accordingly utilities, of GAM327 correlate with, and may be deduced from, the identity of the target genes which GAM327 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[4699] Nucleotide sequences of the GAM327 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM327 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM327 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM327 are further described hereinbelow with reference to Table Table1.

[4700] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM327 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4701]

[4702] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 328 (GAM328) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4703] GAM328 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM328 was detected is described hereinabove with reference to Figs. 2-8.

[4704] GAM328 gene, herein designated GAM GENE, and GAM328 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4705] GAM328 gene, herein designated GAM GENE, encodes a GAM328 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM328 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM328 precursor RNA is designated SEQ ID:4987, and is provided hereinbelow with reference to the sequence listing part.

[4706] GAM328 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM328 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[4707] An enzyme complex designated DICER COMPLEX, dices the GAM328 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM328 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM328 RNA is designated SEQ ID:4988, and is provided hereinbelow with reference to the sequence listing part.

[4708] GAM328 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM328 target RNA, herein designated GAM TARGET RNA. GAM328 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4709] GAM328 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM328 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM328 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM328 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM328 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4710] The complementary binding of GAM328 RNA, herein designated GAM RNA, to target binding sites on GAM328 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM328 target RNA, herein designated GAM TARGET RNA, into GAM328 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4711] It is appreciated that GAM328 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM328 target genes. The mRNA of each one of this plurality of GAM328 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM328 RNA, herein designated GAM RNA, and which when bound by GAM328 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM328 target proteins.

[4712] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM328 gene, herein designated GAM GENE, on one or more GAM328 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4713] It is yet further appreciated that specific functions, and accordingly utilities, of GAM328 correlate with, and may be deduced from, the identity of the target genes which GAM328 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4714] Nucleotide sequences of the GAM328 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM328 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM328 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM328 are further described hereinbelow with reference to Table Table1.

[4715] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM328 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4716]

[4717] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 329 (GAM329) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4718] GAM329 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM329 was detected is described hereinabove with reference to Figs. 2-8.

[4719] GAM329 gene, herein designated GAM GENE, and GAM329 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4720] GAM329 gene, herein designated GAM GENE, encodes a GAM329 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM329 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM329 precursor RNA is designated SEQ ID:5001, and is provided hereinbelow with reference to the sequence listing part.

[4721] GAM329 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM329 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4722] An enzyme complex designated DICER COMPLEX, dices the GAM329 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM329 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 30%) nucleotide sequence of GAM329 RNA is designated SEQ ID:5002, and is provided hereinbelow with reference to the sequence listing part.

[4723] GAM329 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM329

target RNA, herein designated GAM TARGET RNA.

GAM329 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4724] GAM329 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM329 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM329 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM329 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM329 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4725] The complementary binding of GAM329 RNA, herein designated GAM RNA, to target binding sites on GAM329 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM329 target RNA, herein designated GAM TARGET RNA, into GAM329 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4726] It is appreciated that GAM329 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM329 target genes. The mRNA of each one of this plurality of GAM329 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM329 RNA, herein designated GAM RNA, and which when bound by GAM329 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM329 target proteins.

[4727] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM329 gene, herein designated GAM GENE, on one or more GAM329 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4728] It is yet further appreciated that specific functions, and accordingly utilities, of GAM329 correlate with, and may be deduced from, the identity of the target genes which GAM329 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4729] Nucleotide sequences of the GAM329 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM329 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM329 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM329 are further described hereinbelow with reference to Table Table1.

[4730] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM329 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4731]

[4732] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 330 (GAM330) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4733] GAM330 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM330 was detected is described hereinabove with reference to Figs. 2-8.

[4734] GAM330 gene, herein designated GAM GENE, and GAM330 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4735] GAM330 gene, herein designated GAM GENE, encodes a GAM330 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM330 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM330 precursor RNA is designated SEQ ID:5006, and is provided hereinbelow with reference to the sequence listing part.

[4736] GAM330 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM330 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4737] An enzyme complex designated DICER COMPLEX, dices the GAM330 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM330 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM330 RNA is designated SEQ ID:5007, and is provided hereinbelow with reference to the sequence listing part.

[4738] GAM330 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM330 target RNA, herein designated GAM TARGET RNA. GAM330 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4739] GAM330 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM330 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM330 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM330 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM330 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4740] The complementary binding of GAM330 RNA, herein designated GAM RNA, to target binding sites on GAM330 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM330 target RNA, herein designated GAM TARGET RNA, into GAM330 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4741] It is appreciated that GAM330 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM330 target genes. The mRNA of each one of this plu-

rality of GAM330 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM330 RNA, herein designated GAM RNA, and which when bound by GAM330 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM330 target proteins.

[4742] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM330 gene, herein designated GAM GENE, on one or more GAM330 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4743] It is yet further appreciated that specific functions, and accordingly utilities, of GAM330 correlate with, and may be deduced from, the identity of the target genes which GAM330 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4744] Nucleotide sequences of the GAM330 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM330 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM330 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM330 are further described hereinbelow with reference to Table Table1.

[4745] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM330 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4746]

[4747] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 331 (GAM331) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[4748] GAM331 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM331 was detected is described hereinabove with reference to Figs. 2-8.

[4749] GAM331 gene, herein designated GAM GENE, and GAM331 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4750] GAM331 gene, herein designated GAM GENE, encodes a GAM331 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM331 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM331 precursor RNA is designated SEQ ID:5078, and is provided hereinbelow with reference to the sequence listing part.

[4751] GAM331 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM331 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4752] An enzyme complex designated DICER COMPLEX, dices the GAM331 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM331 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 50%) nucleotide sequence of GAM331 RNA is designated SEQ ID:5079, and is provided hereinbelow with reference to the sequence listing part.

[4753] GAM331 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM331 target RNA, herein designated GAM TARGET RNA.
GAM331 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[4754] GAM331 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM331 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM331 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM331 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM331 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4755] The complementary binding of GAM331 RNA, herein designated GAM RNA, to target binding sites on GAM331 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM331 target RNA, herein designated GAM TARGET RNA, into GAM331 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4756] It is appreciated that GAM331 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM331 target genes. The mRNA of each one of this plurality of GAM331 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM331 RNA, herein designated GAM RNA, and which when bound by GAM331 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM331 target proteins.

[4757] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM331 gene, herein designated GAM GENE, on one or more GAM331 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4758] It is yet further appreciated that specific functions, and accordingly utilities, of GAM331 correlate with, and may be deduced from, the identity of the target genes which GAM331 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4759] Nucleotide sequences of the GAM331 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM331 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM331 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM331 are further described hereinbelow with reference to Table Table1.

[4760] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM331 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4761]

[4762] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 332 (GAM332) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4763] GAM332 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM332 was detected is described hereinabove with reference to Figs. 2-8.

[4764] GAM332 gene, herein designated GAM GENE, and GAM332 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4765] GAM332 gene, herein designated GAM GENE, encodes a GAM332 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM332 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM332 precursor RNA is designated SEQ ID:5105, and is provided hereinbelow with reference to the sequence listing part.

[4766] GAM332 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM332 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4767] An enzyme complex designated DICER COMPLEX, dices the GAM332 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM332 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of

GAM332 RNA is designated SEQ ID:5106, and is provided hereinbelow with reference to the sequence listing part.

[4768] GAM332 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM332 target RNA, herein designated GAM TARGET RNA. GAM332 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4769] GAM332 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM332 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM332 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM332 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM332 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4770] The complementary binding of GAM332 RNA, herein designated GAM RNA, to target binding sites on GAM332 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM332 target RNA, herein designated GAM TARGET RNA, into GAM332 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4771] It is appreciated that GAM332 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM332 target genes. The mRNA of each one of this plurality of GAM332 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM332 RNA, herein designated GAM RNA, and which when bound by GAM332 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM332 target proteins.

[4772] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM332 gene, herein designated GAM GENE, on one or more GAM332 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4773] It is yet further appreciated that specific functions, and accordingly utilities, of GAM332 correlate with, and may be deduced from, the identity of the target genes which GAM332 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4774] Nucleotide sequences of the GAM332 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM332 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM332 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM332 are further described hereinbelow with reference to Table Table1.

[4775] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM332 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4776]

[4777] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 333 (GAM333) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4778] GAM333 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM333 was detected is described hereinabove

with reference to Figs. 2-8.

[4779] GAM333 gene, herein designated GAM GENE, and GAM333 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4780] GAM333 gene, herein designated GAM GENE, encodes a GAM333 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM333 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM333 precursor RNA is designated SEQ ID:5123, and is provided hereinbelow with reference to the sequence listing part.

[4781] GAM333 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM333 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4782] An enzyme complex designated DICER COMPLEX, dices the GAM333 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM333 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 26%) nucleotide sequence of GAM333 RNA is designated SEQ ID:5124, and is provided hereinbelow with reference to the sequence listing part.

[4783] GAM333 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM333 target RNA, herein designated GAM TARGET RNA. GAM333 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4784] GAM333 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM333 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM333 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM333 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM333 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4785] The complementary binding of GAM333 RNA, herein designated GAM RNA, to target binding sites on GAM333 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM333 target RNA, herein designated GAM TARGET RNA, into GAM333 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[4786] It is appreciated that GAM333 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM333 target genes. The mRNA of each one of this plurality of GAM333 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM333 RNA, herein designated GAM RNA, and which when bound by GAM333 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM333 target proteins.

[4787] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM333 gene, herein designated GAM GENE, on one or more GAM333 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4788] It is yet further appreciated that specific functions, and accordingly utilities, of GAM333 correlate with, and may be deduced from, the identity of the target genes which GAM333 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4789] Nucleotide sequences of the GAM333 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM333 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM333 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM333 are further described hereinbelow with reference to Table Table1.

[4790] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM333 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4791]

[4792] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 334 (GAM334) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4793] GAM334 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM334 was detected is described hereinabove with reference to Figs. 2-8.

[4794] GAM334 gene, herein designated GAM GENE, and GAM334 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4795] GAM334 gene, herein designated GAM GENE, encodes a GAM334 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM334 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM334 precursor RNA is designated SEQ ID:5135, and is provided hereinbelow with reference to the sequence listing part.

[4796] GAM334 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM334 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4797] An enzyme complex designated DICER COMPLEX, dices the GAM334 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM334 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 38%) nucleotide sequence of GAM334 RNA is designated SEQ ID:5136, and is provided hereinbelow with reference to the sequence listing part.

[4798] GAM334 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM334 target RNA, herein designated GAM TARGET RNA.

GAM334 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4799] GAM334 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM334 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM334 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM334 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM334 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4800] The complementary binding of GAM334 RNA, herein designated GAM RNA, to target binding sites on GAM334 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM334 target RNA, herein designated GAM TARGET RNA, into GAM334 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4801] It is appreciated that GAM334 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM334 target genes. The mRNA of each one of this plurality of GAM334 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM334 RNA, herein designated GAM RNA, and which when bound by GAM334 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM334 target proteins.

[4802] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM334 gene, herein designated GAM GENE, on one or more GAM334 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4803] It is yet further appreciated that specific functions, and accordingly utilities, of GAM334 correlate with, and may be deduced from, the identity of the target genes which GAM334 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4804] Nucleotide sequences of the GAM334 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM334 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM334 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM334 are further described hereinbelow with reference to Table Table1.

[4805] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM334 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4806]

[4807] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 335 (GAM335) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4808] GAM335 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM335 was detected is described hereinabove with reference to Figs. 2-8.

[4809] GAM335 gene, herein designated GAM GENE, and GAM335 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4810] GAM335 gene, herein designated GAM GENE, encodes a

GAM335 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM335 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM335 precursor RNA is designated SEQ ID:5145, and is provided hereinbelow with reference to the sequence listing part.

[4811] GAM335 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM335 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4812] An enzyme complex designated DICER COMPLEX, dices the GAM335 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM335 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM335 RNA is designated SEQ ID:5146, and is provided hereinbelow with reference to the sequence listing part.

[4813] GAM335 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM335 target RNA, herein designated GAM TARGET RNA. GAM335 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4814] GAM335 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM335 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM335 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM335 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM335 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4815] The complementary binding of GAM335 RNA, herein designated GAM RNA, to target binding sites on GAM335 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM335 target RNA, herein designated GAM TARGET RNA, into GAM335 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4816] It is appreciated that GAM335 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM335 target genes. The mRNA of each one of this plurality of GAM335 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM335 RNA, herein designated GAM RNA, and which when bound by GAM335 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM335 target proteins.

[4817] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM335 gene, herein designated GAM GENE, on one or more GAM335 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4818] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM335 correlate with, and may be deduced from, the identity of the target genes which GAM335 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4819] Nucleotide sequences of the GAM335 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM335 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM335 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM335 are further described hereinbelow with reference to Table Table1.

[4820] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM335 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4821]

[4822] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 336 (GAM336) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[4823] GAM336 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM336 was detected is described hereinabove with reference to Figs. 2-8.

[4824] GAM336 gene, herein designated GAM GENE, and GAM336 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4825] GAM336 gene, herein designated GAM GENE, encodes a GAM336 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM336 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM336 precursor RNA is designated SEQ ID:5161, and is provided hereinbelow with reference to the sequence listing part.

[4826] GAM336 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM336 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4827] An enzyme complex designated DICER COMPLEX, dices the GAM336 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM336 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 73%) nucleotide sequence of GAM336 RNA is designated SEQ ID:5162, and is provided hereinbelow with reference to the sequence listing part.

[4828] GAM336 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM336 target RNA, herein designated GAM TARGET RNA.
GAM336 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4829] GAM336 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM336 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM336 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM336 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM336 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4830] The complementary binding of GAM336 RNA, herein designated GAM RNA, to target binding sites on GAM336 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM336 target RNA, herein designated GAM TARGET RNA, into GAM336 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4831] It is appreciated that GAM336 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM336 target genes. The mRNA of each one of this plurality of GAM336 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM336 RNA, herein designated GAM RNA, and which when bound by GAM336 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM336 target proteins.

[4832] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM336 gene, herein designated GAM GENE, on one or more GAM336 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4833] It is yet further appreciated that specific functions, and accordingly utilities, of GAM336 correlate with, and may be deduced from, the identity of the target genes which GAM336 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4834] Nucleotide sequences of the GAM336 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM336 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM336 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM336 are further described hereinbelow with reference to Table Table1.

[4835] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM336 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4836]

[4837] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 337 (GAM337) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4838] GAM337 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM337 was detected is described hereinabove with reference to Figs. 2-8.

[4839] GAM337 gene, herein designated GAM GENE, and GAM337 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4840] GAM337 gene, herein designated GAM GENE, encodes a GAM337 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM337 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM337 precursor RNA is designated SEQ ID:5176, and is provided hereinbelow with reference to the sequence listing part.

[4841] GAM337 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM337 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4842] An enzyme complex designated DICER COMPLEX, dices the GAM337 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM337 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM337 RNA is designated SEQ ID:5177, and is provided

hereinbelow with reference to the sequence listing part.

[4843] GAM337 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM337 target RNA, herein designated GAM TARGET RNA.
GAM337 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4844] GAM337 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM337 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM337 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM337 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM337 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4845] The complementary binding of GAM337 RNA, herein designated GAM RNA, to target binding sites on GAM337 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM337 target RNA, herein designated GAM TARGET RNA, into GAM337 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4846] It is appreciated that GAM337 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM337 target genes. The mRNA of each one of this plurality of GAM337 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM337 RNA, herein designated GAM RNA, and which when bound by GAM337 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM337 tar-

get proteins.

[4847] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM337 gene, herein designated GAM GENE, on one or more GAM337 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4848] It is yet further appreciated that specific functions, and accordingly utilities, of GAM337 correlate with, and may be deduced from, the identity of the target genes which GAM337 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4849] Nucleotide sequences of the GAM337 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM337 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM337 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM337 are further described hereinbelow with reference to Table Table1.

[4850] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM337 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4851]

[4852] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 338 (GAM338) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4853] GAM338 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM338 was detected is described hereinabove with reference to Figs. 2-8.

[4854] GAM338 gene, herein designated GAM GENE, and GAM338 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4855] GAM338 gene, herein designated GAM GENE, encodes a GAM338 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM338 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM338 precursor RNA is designated SEQ ID:5197, and is provided hereinbelow with reference to the sequence listing part.

[4856] GAM338 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM338 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4857] An enzyme complex designated DICER COMPLEX, dices

the GAM338 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM338 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM338 RNA is designated SEQ ID:5198, and is provided hereinbelow with reference to the sequence listing part.

[4858] GAM338 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM338 target RNA, herein designated GAM TARGET RNA. GAM338 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4859] GAM338 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM338 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM338

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM338 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM338 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4860] The complementary binding of GAM338 RNA, herein designated GAM RNA, to target binding sites on GAM338 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM338 target RNA, herein designated GAM TARGET RNA, into GAM338 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4861] It is appreciated that GAM338 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM338 target genes. The mRNA of each one of this plurality of GAM338 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM338 RNA, herein designated GAM RNA, and which when bound by GAM338 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM338 target proteins.

[4862] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM338 gene, herein designated GAM GENE, on one or more GAM338 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4863] It is yet further appreciated that specific functions, and accordingly utilities, of GAM338 correlate with, and may be deduced from, the identity of the target genes which GAM338 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4864] Nucleotide sequences of the GAM338 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM338 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM338 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM338 are further described hereinbelow with reference to Table Table1.

[4865] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM338 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4866]

[4867] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 339 (GAM339) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4868] GAM339 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM339 was detected is described hereinabove with reference to Figs. 2-8.

[4869] GAM339 gene, herein designated GAM GENE, and GAM339 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4870] GAM339 gene, herein designated GAM GENE, encodes a GAM339 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM339 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM339 precursor RNA is designated SEQ ID:5213, and is provided hereinbelow with reference to the sequence listing part.

[4871] GAM339 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM339 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4872] An enzyme complex designated DICER COMPLEX, dices the GAM339 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM339 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM339 RNA is designated SEQ ID:5214, and is provided hereinbelow with reference to the sequence listing part.

[4873] GAM339 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM339 target RNA, herein designated GAM TARGET RNA. GAM339 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4874] GAM339 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM339 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM339 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM339 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM339 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[4875] The complementary binding of GAM339 RNA, herein designated GAM RNA, to target binding sites on GAM339 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM339 target RNA, herein designated GAM TARGET RNA, into GAM339 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4876] It is appreciated that GAM339 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM339 target genes. The mRNA of each one of this plurality of GAM339 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM339 RNA, herein designated GAM RNA, and which when bound by GAM339 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM339 target proteins.

[4877] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM339 gene, herein designated GAM GENE, on one or

more GAM339 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4878] It is yet further appreciated that specific functions, and accordingly utilities, of GAM339 correlate with, and may be deduced from, the identity of the target genes which GAM339 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4879] Nucleotide sequences of the GAM339 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM339 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM339 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM339 are further de-

scribed hereinbelow with reference to Table Table1.

[4880] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM339 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4881]

[4882] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 340 (GAM340) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4883] GAM340 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM340 was detected is described hereinabove with reference to Figs. 2-8.

[4884] GAM340 gene, herein designated GAM GENE, and GAM340 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4885] GAM340 gene, herein designated GAM GENE, encodes a GAM340 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM340 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM340 precursor RNA is designated SEQ ID:5220, and is provided hereinbelow with reference to the sequence listing part.

[4886] GAM340 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM340 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4887] An enzyme complex designated DICER COMPLEX, dices the GAM340 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM340 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM340 RNA is designated SEQ ID:5221, and is provided hereinbelow with reference to the sequence listing part.

[4888] GAM340 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM340 target RNA, herein designated GAM TARGET RNA. GAM340 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4889] GAM340 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM340 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM340 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM340 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM340 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4890] The complementary binding of GAM340 RNA, herein designated GAM RNA, to target binding sites on GAM340 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM340 target RNA, herein designated GAM TARGET RNA, into GAM340 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4891] It is appreciated that GAM340 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM340 target genes. The mRNA of each one of this plurality of GAM340 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM340 RNA, herein designated GAM RNA, and which when bound by GAM340 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM340 target proteins.

[4892] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM340 gene, herein designated GAM GENE, on one or more GAM340 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4893] It is yet further appreciated that specific functions, and accordingly utilities, of GAM340 correlate with, and may

be deduced from, the identity of the target genes which GAM340 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4894] Nucleotide sequences of the GAM340 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM340 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM340 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM340 are further described hereinbelow with reference to Table Table1.

[4895] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM340 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4896]

[4897] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 341 (GAM341) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4898] GAM341 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM341 was detected is described hereinabove with reference to Figs. 2-8.

[4899] GAM341 gene, herein designated GAM GENE, and GAM341 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4900] GAM341 gene, herein designated GAM GENE, encodes a GAM341 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM341 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM341 precursor RNA is designated SEQ ID:5228, and is provided hereinbelow with reference to the sequence listing part.

[4901] GAM341 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM341 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4902] An enzyme complex designated DICER COMPLEX, dices the GAM341 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM341 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM341 RNA is designated SEQ ID:5229, and is provided hereinbelow with reference to the sequence listing part.

[4903] GAM341 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM341 target RNA, herein designated GAM TARGET RNA. GAM341 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4904] GAM341 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM341 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM341 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM341 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM341 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4905] The complementary binding of GAM341 RNA, herein designated GAM RNA, to target binding sites on GAM341 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM341 target RNA, herein designated GAM TARGET RNA, into GAM341 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4906] It is appreciated that GAM341 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM341 target genes. The mRNA of each one of this plurality of GAM341 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM341 RNA, herein designated GAM RNA, and which when bound by GAM341 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM341 target proteins.

[4907] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM341 gene, herein designated GAM GENE, on one or more GAM341 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4908] It is yet further appreciated that specific functions, and accordingly utilities, of GAM341 correlate with, and may be deduced from, the identity of the target genes which GAM341 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4909] Nucleotide sequences of the GAM341 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM341 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM341 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM341 are further described hereinbelow with reference to Table Table1.

[4910] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM341 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4911]

[4912] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 342 (GAM342) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4913] GAM342 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM342 was detected is described hereinabove with reference to Figs. 2-8.

[4914] GAM342 gene, herein designated GAM GENE, and GAM342 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4915] GAM342 gene, herein designated GAM GENE, encodes a GAM342 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM342 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM342 precursor RNA is desig-

nated SEQ ID:5248, and is provided hereinbelow with reference to the sequence listing part.

[4916] GAM342 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM342 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4917] An enzyme complex designated DICER COMPLEX, dices the GAM342 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM342 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM342 RNA is designated SEQ ID:5249, and is provided hereinbelow with reference to the sequence listing part.

[4918] GAM342 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM342 target RNA, herein designated GAM TARGET RNA. GAM342 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4919] GAM342 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM342 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM342 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM342 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM342

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4920] The complementary binding of GAM342 RNA, herein designated GAM RNA, to target binding sites on GAM342 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM342 target RNA, herein designated GAM TARGET RNA, into GAM342 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4921] It is appreciated that GAM342 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM342 target genes. The mRNA of each one of this plurality of GAM342 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM342 RNA, herein designated GAM RNA, and which when bound by GAM342 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM342 target proteins.

[4922] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM342 gene, herein designated GAM GENE, on one or more GAM342 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4923] It is yet further appreciated that specific functions, and accordingly utilities, of GAM342 correlate with, and may be deduced from, the identity of the target genes which GAM342 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4924] Nucleotide sequences of the GAM342 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM342 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM342 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM342 are further described hereinbelow with reference to Table Table1.

[4925] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM342 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4926]

[4927] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 343 (GAM343) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4928] GAM343 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM343 was detected is described hereinabove with reference to Figs. 2-8.

[4929] GAM343 gene, herein designated GAM GENE, and

GAM343 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4930] GAM343 gene, herein designated GAM GENE, encodes a GAM343 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM343 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM343 precursor RNA is designated SEQ ID:5284, and is provided hereinbelow with reference to the sequence listing part.

[4931] GAM343 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM343 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4932] An enzyme complex designated DICER COMPLEX, dices the GAM343 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM343 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM343 RNA is designated SEQ ID:5285, and is provided hereinbelow with reference to the sequence listing part.

[4933] GAM343 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM343 target RNA, herein designated GAM TARGET RNA. GAM343 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4934] GAM343 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM343 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM343 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM343 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM343 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4935] The complementary binding of GAM343 RNA, herein designated GAM RNA, to target binding sites on GAM343 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM343 target RNA, herein designated GAM TARGET RNA, into GAM343 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4936] It is appreciated that GAM343 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM343 target genes. The mRNA of each one of this plurality of GAM343 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM343 RNA, herein designated GAM RNA, and which when bound by GAM343 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM343 target proteins.

[4937] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM343 gene, herein designated GAM GENE, on one or more GAM343 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4938] It is yet further appreciated that specific functions, and accordingly utilities, of GAM343 correlate with, and may be deduced from, the identity of the target genes which GAM343 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4939] Nucleotide sequences of the GAM343 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM343 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM343 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM343 are further described hereinbelow with reference to Table Table1.

[4940] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM343 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4941]

[4942] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 344 (GAM344) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4943] GAM344 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM344 was detected is described hereinabove with reference to Figs. 2-8.

[4944] GAM344 gene, herein designated GAM GENE, and GAM344 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4945] GAM344 gene, herein designated GAM GENE, encodes a GAM344 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM344 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM344 precursor RNA is designated SEQ ID:5296, and is provided hereinbelow with reference to the sequence listing part.

[4946] GAM344 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM344 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4947] An enzyme complex designated DICER COMPLEX, dices the GAM344 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM344 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM344 RNA is designated SEQ ID:5297, and is provided hereinbelow with reference to the sequence listing part.

[4948] GAM344 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM344 target RNA, herein designated GAM TARGET RNA. GAM344 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4949] GAM344 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM344 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM344 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM344 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM344 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4950] The complementary binding of GAM344 RNA, herein designated GAM RNA, to target binding sites on GAM344 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM344 target RNA, herein designated GAM TARGET RNA, into GAM344 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4951] It is appreciated that GAM344 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM344 target genes. The mRNA of each one of this plurality of GAM344 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM344 RNA, herein designated GAM RNA, and which when bound by GAM344 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM344 target proteins.

[4952] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM344 gene, herein designated GAM GENE, on one or more GAM344 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4953] It is yet further appreciated that specific functions, and accordingly utilities, of GAM344 correlate with, and may be deduced from, the identity of the target genes which GAM344 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4954] Nucleotide sequences of the GAM344 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM344 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM344 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM344 are further described hereinbelow with reference to Table Table1.

[4955] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM344 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4956]

[4957] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 345 (GAM345) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4958] GAM345 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM345 was detected is described hereinabove with reference to Figs. 2-8.

[4959] GAM345 gene, herein designated GAM GENE, and GAM345 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4960] GAM345 gene, herein designated GAM GENE, encodes a GAM345 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM345 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM345 precursor RNA is designated SEQ ID:5306, and is provided hereinbelow with reference to the sequence listing part.

[4961] GAM345 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM345 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4962] An enzyme complex designated DICER COMPLEX, dices the GAM345 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM345 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM345 RNA is designated SEQ ID:5307, and is provided hereinbelow with reference to the sequence listing part.

[4963] GAM345 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM345 target RNA, herein designated GAM TARGET RNA. GAM345 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4964] GAM345 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM345 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM345 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM345 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM345 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4965] The complementary binding of GAM345 RNA, herein designated GAM RNA, to target binding sites on GAM345 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM345 target RNA, herein designated GAM TARGET RNA, into GAM345 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4966] It is appreciated that GAM345 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM345 target genes. The mRNA of each one of this plurality of GAM345 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM345 RNA,

herein designated GAM RNA, and which when bound by GAM345 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM345 target proteins.

[4967] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM345 gene, herein designated GAM GENE, on one or more GAM345 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4968] It is yet further appreciated that specific functions, and accordingly utilities, of GAM345 correlate with, and may be deduced from, the identity of the target genes which

GAM345 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4969] Nucleotide sequences of the GAM345 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM345 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM345 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM345 are further described hereinbelow with reference to Table Table1.

[4970] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM345 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[4971]

[4972] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 346 (GAM346) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4973] GAM346 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM346 was detected is described hereinabove with reference to Figs. 2-8.

[4974] GAM346 gene, herein designated GAM GENE, and GAM346 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4975] GAM346 gene, herein designated GAM GENE, encodes a GAM346 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM346 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM346 precursor RNA is designated SEQ ID:5337, and is provided hereinbelow with reference to the sequence listing part.

[4976] GAM346 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM346 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[4977] An enzyme complex designated DICER COMPLEX, dices the GAM346 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM346 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM346 RNA is designated SEQ ID:5338, and is provided hereinbelow with reference to the sequence listing part.

[4978] GAM346 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM346 target RNA, herein designated GAM TARGET RNA.
GAM346 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4979] GAM346 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM346 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM346 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM346 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM346 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4980] The complementary binding of GAM346 RNA, herein designated GAM RNA, to target binding sites on GAM346 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM346 target RNA, herein desig-

nated GAM TARGET RNA, into GAM346 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4981] It is appreciated that GAM346 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM346 target genes. The mRNA of each one of this plurality of GAM346 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM346 RNA, herein designated GAM RNA, and which when bound by GAM346 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM346 target proteins.

[4982] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM346 gene, herein designated GAM GENE, on one or more GAM346 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4983] It is yet further appreciated that specific functions, and accordingly utilities, of GAM346 correlate with, and may be deduced from, the identity of the target genes which GAM346 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4984] Nucleotide sequences of the GAM346 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM346 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM346 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM346 are further described hereinbelow with reference to Table Table1.

[4985] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM346 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[4986]

[4987] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 347 (GAM347) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[4988] GAM347 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM347 was detected is described hereinabove with reference to Figs. 2-8.

[4989] GAM347 gene, herein designated GAM GENE, and GAM347 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[4990] GAM347 gene, herein designated GAM GENE, encodes a GAM347 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM347 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM347 precursor RNA is designated SEQ ID:5348, and is provided hereinbelow with ref-

erence to the sequence listing part.

[4991] GAM347 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM347 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[4992] An enzyme complex designated DICER COMPLEX, dices the GAM347 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM347 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM347 RNA is designated SEQ ID:5349, and is provided hereinbelow with reference to the sequence listing part.

[4993] GAM347 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM347 target RNA, herein designated GAM TARGET RNA.

GAM347 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[4994] GAM347 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM347 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM347 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM347 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM347 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[4995] The complementary binding of GAM347 RNA, herein designated GAM RNA, to target binding sites on GAM347 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM347 target RNA, herein designated GAM TARGET RNA, into GAM347 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[4996] It is appreciated that GAM347 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM347 target genes. The mRNA of each one of this plurality of GAM347 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM347 RNA, herein designated GAM RNA, and which when bound by GAM347 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM347 target proteins.

[4997] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM347 gene, herein designated GAM GENE, on one or more GAM347 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[4998] It is yet further appreciated that specific functions, and accordingly utilities, of GAM347 correlate with, and may be deduced from, the identity of the target genes which GAM347 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[4999] Nucleotide sequences of the GAM347 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM347 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM347 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM347 are further described hereinbelow with reference to Table Table1.

[5000] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM347 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5001]

[5002] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 348 (GAM348) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5003] GAM348 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM348 was detected is described hereinabove with reference to Figs. 2-8.

[5004] GAM348 gene, herein designated GAM GENE, and GAM348 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[5005] GAM348 gene, herein designated GAM GENE, encodes a GAM348 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM348 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM348 precursor RNA is designated SEQ ID:5360, and is provided hereinbelow with reference to the sequence listing part.

[5006] GAM348 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM348 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5007] An enzyme complex designated DICER COMPLEX, dices the GAM348 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM348 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM348 RNA is designated SEQ ID:5361, and is provided hereinbelow with reference to the sequence listing part.

[5008] GAM348 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM348 target RNA, herein designated GAM TARGET RNA. GAM348 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5009] GAM348 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM348 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM348 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM348 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM348 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5010] The complementary binding of GAM348 RNA, herein designated GAM RNA, to target binding sites on GAM348 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM348 target RNA, herein designated GAM TARGET RNA, into GAM348 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5011] It is appreciated that GAM348 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM348 target genes. The mRNA of each one of this plurality of GAM348 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM348 RNA, herein designated GAM RNA, and which when bound by GAM348 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM348 target proteins.

[5012] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM348 gene, herein designated GAM GENE, on one or more GAM348 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[5013] It is yet further appreciated that specific functions, and accordingly utilities, of GAM348 correlate with, and may be deduced from, the identity of the target genes which GAM348 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5014] Nucleotide sequences of the GAM348 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM348 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM348 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM348 are further described hereinbelow with reference to Table Table1.

[5015] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM348 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5016]

[5017] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

349 (GAM349) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5018] GAM349 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM349 was detected is described hereinabove with reference to Figs. 2-8.

[5019] GAM349 gene, herein designated GAM GENE, and GAM349 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5020] GAM349 gene, herein designated GAM GENE, encodes a GAM349 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM349 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM349 precursor RNA is designated SEQ ID:5370, and is provided hereinbelow with reference to the sequence listing part.

[5021] GAM349 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM349 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5022] An enzyme complex designated DICER COMPLEX, dices the GAM349 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM349 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 86%) nucleotide sequence of GAM349 RNA is designated SEQ ID:5371, and is provided hereinbelow with reference to the sequence listing part.

[5023] GAM349 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM349 target RNA, herein designated GAM TARGET RNA. GAM349 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5024] GAM349 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM349 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM349 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM349 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM349 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5025] The complementary binding of GAM349 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM349 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM349 target RNA, herein designated GAM TARGET RNA, into GAM349 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5026] It is appreciated that GAM349 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM349 target genes. The mRNA of each one of this plurality of GAM349 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM349 RNA, herein designated GAM RNA, and which when bound by GAM349 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM349 target proteins.

[5027] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM349 gene, herein designated GAM GENE, on one or more GAM349 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5028] It is yet further appreciated that specific functions, and accordingly utilities, of GAM349 correlate with, and may be deduced from, the identity of the target genes which GAM349 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5029] Nucleotide sequences of the GAM349 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM349 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM349 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM349 are further described hereinbelow with reference to Table Table1.

[5030] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM349 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5031]

[5032] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 350 (GAM350) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5033] GAM350 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM350 was detected is described hereinabove with reference to Figs. 2-8.

[5034] GAM350 gene, herein designated GAM GENE, and GAM350 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5035] GAM350 gene, herein designated GAM GENE, encodes a GAM350 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM350 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM350 precursor RNA is designated SEQ ID:5379, and is provided hereinbelow with reference to the sequence listing part.

[5036] GAM350 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM350 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5037] An enzyme complex designated DICER COMPLEX, dices the GAM350 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM350 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 66%) nucleotide sequence of GAM350 RNA is designated SEQ ID:5380, and is provided hereinbelow with reference to the sequence listing part.

[5038] GAM350 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM350 target RNA, herein designated GAM TARGET RNA. GAM350 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5039] GAM350 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM350 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM350 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM350 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM350 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5040] The complementary binding of GAM350 RNA, herein designated GAM RNA, to target binding sites on GAM350 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM350 target RNA, herein designated GAM TARGET RNA, into GAM350 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5041] It is appreciated that GAM350 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM350 target genes. The mRNA of each one of this plurality of GAM350 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM350 RNA, herein designated GAM RNA, and which when bound by

GAM350 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM350 target proteins.

[5042] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM350 gene, herein designated GAM GENE, on one or more GAM350 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5043] It is yet further appreciated that specific functions, and accordingly utilities, of GAM350 correlate with, and may be deduced from, the identity of the target genes which GAM350 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[5044] Nucleotide sequences of the GAM350 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM350 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM350 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM350 are further described hereinbelow with reference to Table Table1.

[5045] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM350 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5046]

[5047] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 351 (GAM351) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5048] GAM351 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM351 was detected is described hereinabove with reference to Figs. 2-8.

[5049] GAM351 gene, herein designated GAM GENE, and GAM351 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5050] GAM351 gene, herein designated GAM GENE, encodes a GAM351 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM351 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM351 precursor RNA is designated SEQ ID:5384, and is provided hereinbelow with reference to the sequence listing part.

[5051] GAM351 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM351 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[5052] An enzyme complex designated DICER COMPLEX, dices the GAM351 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM351 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM351 RNA is designated SEQ ID:5385, and is provided hereinbelow with reference to the sequence listing part.

[5053] GAM351 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM351 target RNA, herein designated GAM TARGET RNA. GAM351 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5054] GAM351 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM351 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM351 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM351 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM351 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5055] The complementary binding of GAM351 RNA, herein designated GAM RNA, to target binding sites on GAM351 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM351 target RNA, herein designated GAM TARGET RNA, into GAM351 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5056] It is appreciated that GAM351 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM351 target genes. The mRNA of each one of this plurality of GAM351 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM351 RNA, herein designated GAM RNA, and which when bound by GAM351 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM351 target proteins.

[5057] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM351 gene, herein designated GAM GENE, on one or more GAM351 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5058] It is yet further appreciated that specific functions, and accordingly utilities, of GAM351 correlate with, and may be deduced from, the identity of the target genes which GAM351 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5059] Nucleotide sequences of the GAM351 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM351 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM351 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM351 are further described hereinbelow with reference to Table Table1.

[5060] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM351 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5061]

[5062] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 352 (GAM352) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5063] GAM352 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM352 was detected is described hereinabove with reference to Figs. 2-8.

[5064] GAM352 gene, herein designated GAM GENE, and GAM352 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5065] GAM352 gene, herein designated GAM GENE, encodes a GAM352 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM352 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM352 precursor RNA is designated SEQ ID:5401, and is provided hereinbelow with reference to the sequence listing part.

[5066] GAM352 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM352 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5067] An enzyme complex designated DICER COMPLEX, dices the GAM352 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM352 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM352 RNA is designated SEQ ID:5402, and is provided hereinbelow with reference to the sequence listing part.

[5068] GAM352 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM352

target RNA, herein designated GAM TARGET RNA.

GAM352 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5069] GAM352 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM352 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM352 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM352 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM352 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5070] The complementary binding of GAM352 RNA, herein designated GAM RNA, to target binding sites on GAM352 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM352 target RNA, herein designated GAM TARGET RNA, into GAM352 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5071] It is appreciated that GAM352 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM352 target genes. The mRNA of each one of this plurality of GAM352 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM352 RNA, herein designated GAM RNA, and which when bound by GAM352 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM352 target proteins.

[5072] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM352 gene, herein designated GAM GENE, on one or more GAM352 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5073] It is yet further appreciated that specific functions, and accordingly utilities, of GAM352 correlate with, and may be deduced from, the identity of the target genes which GAM352 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5074] Nucleotide sequences of the GAM352 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM352 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM352 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM352 are further described hereinbelow with reference to Table Table1.

[5075] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM352 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5076]

[5077] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 353 (GAM353) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5078] GAM353 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM353 was detected is described hereinabove with reference to Figs. 2-8.

[5079] GAM353 gene, herein designated GAM GENE, and GAM353 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5080] GAM353 gene, herein designated GAM GENE, encodes a GAM353 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM353 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM353 precursor RNA is designated SEQ ID:5418, and is provided hereinbelow with reference to the sequence listing part.

[5081] GAM353 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM353 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5082] An enzyme complex designated DICER COMPLEX, dices the GAM353 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM353 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM353 RNA is designated SEQ ID:5419, and is provided hereinbelow with reference to the sequence listing part.

[5083] GAM353 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM353 target RNA, herein designated GAM TARGET RNA. GAM353 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5084] GAM353 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM353 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM353 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM353 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM353 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5085] The complementary binding of GAM353 RNA, herein designated GAM RNA, to target binding sites on GAM353 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM353 target RNA, herein designated GAM TARGET RNA, into GAM353 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5086] It is appreciated that GAM353 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM353 target genes. The mRNA of each one of this plu-

rality of GAM353 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM353 RNA, herein designated GAM RNA, and which when bound by GAM353 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM353 target proteins.

[5087] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM353 gene, herein designated GAM GENE, on one or more GAM353 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5088] It is yet further appreciated that specific functions, and accordingly utilities, of GAM353 correlate with, and may be deduced from, the identity of the target genes which GAM353 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5089] Nucleotide sequences of the GAM353 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM353 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM353 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM353 are further described hereinbelow with reference to Table Table1.

[5090] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM353 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5091]

[5092] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 354 (GAM354) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[5093] GAM354 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM354 was detected is described hereinabove with reference to Figs. 2-8.

[5094] GAM354 gene, herein designated GAM GENE, and GAM354 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5095] GAM354 gene, herein designated GAM GENE, encodes a GAM354 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM354 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM354 precursor RNA is designated SEQ ID:5459, and is provided hereinbelow with reference to the sequence listing part.

[5096] GAM354 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM354 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5097] An enzyme complex designated DICER COMPLEX, dices the GAM354 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM354 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 85%) nucleotide sequence of GAM354 RNA is designated SEQ ID:5460, and is provided hereinbelow with reference to the sequence listing part.

[5098] GAM354 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM354 target RNA, herein designated GAM TARGET RNA.
GAM354 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[5099] GAM354 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM354 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM354 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM354 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM354 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5100] The complementary binding of GAM354 RNA, herein designated GAM RNA, to target binding sites on GAM354 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM354 target RNA, herein designated GAM TARGET RNA, into GAM354 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5101] It is appreciated that GAM354 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM354 target genes. The mRNA of each one of this plurality of GAM354 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM354 RNA, herein designated GAM RNA, and which when bound by GAM354 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM354 target proteins.

[5102] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM354 gene, herein designated GAM GENE, on one or more GAM354 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5103] It is yet further appreciated that specific functions, and accordingly utilities, of GAM354 correlate with, and may be deduced from, the identity of the target genes which GAM354 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5104] Nucleotide sequences of the GAM354 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM354 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM354 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM354 are further described hereinbelow with reference to Table Table1.

[5105] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM354 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5106]

[5107] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 355 (GAM355) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5108] GAM355 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM355 was detected is described hereinabove with reference to Figs. 2-8.

[5109] GAM355 gene, herein designated GAM GENE, and GAM355 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5110] GAM355 gene, herein designated GAM GENE, encodes a GAM355 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM355 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM355 precursor RNA is designated SEQ ID:5469, and is provided hereinbelow with reference to the sequence listing part.

[5111] GAM355 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM355 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5112] An enzyme complex designated DICER COMPLEX, dices the GAM355 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM355 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 80%) nucleotide sequence of GAM355 RNA is designated SEQ ID:5470, and is provided hereinbelow with reference to the sequence listing part.

[5113] GAM355 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM355

target RNA, herein designated GAM TARGET RNA.

GAM355 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5114] GAM355 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM355 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM355 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM355 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM355 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5115] The complementary binding of GAM355 RNA, herein designated GAM RNA, to target binding sites on GAM355 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM355 target RNA, herein designated GAM TARGET RNA, into GAM355 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5116] It is appreciated that GAM355 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM355 target genes. The mRNA of each one of this plurality of GAM355 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM355 RNA, herein designated GAM RNA, and which when bound by GAM355 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM355 target proteins.

[5117] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM355 gene, herein designated GAM GENE, on one or more GAM355 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5118] It is yet further appreciated that specific functions, and accordingly utilities, of GAM355 correlate with, and may be deduced from, the identity of the target genes which GAM355 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5119] Nucleotide sequences of the GAM355 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM355 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM355 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM355 are further described hereinbelow with reference to Table Table1.

[5120] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM355 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5121]

[5122] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 356 (GAM356) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5123] GAM356 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM356 was detected is described hereinabove with reference to Figs. 2-8.

[5124] GAM356 gene, herein designated GAM GENE, and GAM356 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5125] GAM356 gene, herein designated GAM GENE, encodes a GAM356 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM356 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM356 precursor RNA is designated SEQ ID:5507, and is provided hereinbelow with reference to the sequence listing part.

[5126] GAM356 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM356 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5127] An enzyme complex designated DICER COMPLEX, dices the GAM356 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM356 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM356 RNA is designated SEQ ID:5508, and is provided hereinbelow with reference to the sequence listing part.

[5128] GAM356 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM356 target RNA, herein designated GAM TARGET RNA. GAM356 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5129] GAM356 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM356 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM356 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM356 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM356 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5130] The complementary binding of GAM356 RNA, herein designated GAM RNA, to target binding sites on GAM356 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM356 target RNA, herein designated GAM TARGET RNA, into GAM356 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5131] It is appreciated that GAM356 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM356 target genes. The mRNA of each one of this plu-

rality of GAM356 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM356 RNA, herein designated GAM RNA, and which when bound by GAM356 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM356 target proteins.

[5132] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM356 gene, herein designated GAM GENE, on one or more GAM356 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5133] It is yet further appreciated that specific functions, and accordingly utilities, of GAM356 correlate with, and may be deduced from, the identity of the target genes which GAM356 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5134] Nucleotide sequences of the GAM356 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM356 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM356 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM356 are further described hereinbelow with reference to Table Table1.

[5135] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM356 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5136]

[5137] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 357 (GAM357) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[5138] GAM357 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM357 was detected is described hereinabove with reference to Figs. 2-8.

[5139] GAM357 gene, herein designated GAM GENE, and GAM357 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5140] GAM357 gene, herein designated GAM GENE, encodes a GAM357 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM357 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM357 precursor RNA is designated SEQ ID:5514, and is provided hereinbelow with reference to the sequence listing part.

[5141] GAM357 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM357 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5142] An enzyme complex designated DICER COMPLEX, dices the GAM357 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM357 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 25%) nucleotide sequence of GAM357 RNA is designated SEQ ID:5515, and is provided hereinbelow with reference to the sequence listing part.

[5143] GAM357 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM357 target RNA, herein designated GAM TARGET RNA. GAM357 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[5144] GAM357 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM357 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM357 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM357 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM357 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5145] The complementary binding of GAM357 RNA, herein designated GAM RNA, to target binding sites on GAM357 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM357 target RNA, herein designated GAM TARGET RNA, into GAM357 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5146] It is appreciated that GAM357 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM357 target genes. The mRNA of each one of this plurality of GAM357 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM357 RNA, herein designated GAM RNA, and which when bound by GAM357 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM357 target proteins.

[5147] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM357 gene, herein designated GAM GENE, on one or more GAM357 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5148] It is yet further appreciated that specific functions, and accordingly utilities, of GAM357 correlate with, and may be deduced from, the identity of the target genes which GAM357 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5149] Nucleotide sequences of the GAM357 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM357 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM357 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM357 are further described hereinbelow with reference to Table Table1.

[5150] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM357 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5151]

[5152] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 358 (GAM358) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5153] GAM358 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM358 was detected is described hereinabove with reference to Figs. 2-8.

[5154] GAM358 gene, herein designated GAM GENE, and GAM358 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5155] GAM358 gene, herein designated GAM GENE, encodes a GAM358 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM358 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM358 precursor RNA is designated SEQ ID:5522, and is provided hereinbelow with reference to the sequence listing part.

[5156] GAM358 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM358 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5157] An enzyme complex designated DICER COMPLEX, dices the GAM358 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM358 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of

GAM358 RNA is designated SEQ ID:5523, and is provided hereinbelow with reference to the sequence listing part.

[5158] GAM358 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM358 target RNA, herein designated GAM TARGET RNA. GAM358 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5159] GAM358 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM358 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM358 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM358 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM358 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5160] The complementary binding of GAM358 RNA, herein designated GAM RNA, to target binding sites on GAM358 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM358 target RNA, herein designated GAM TARGET RNA, into GAM358 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5161] It is appreciated that GAM358 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM358 target genes. The mRNA of each one of this plurality of GAM358 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM358 RNA, herein designated GAM RNA, and which when bound by GAM358 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM358 target proteins.

[5162] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM358 gene, herein designated GAM GENE, on one or more GAM358 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5163] It is yet further appreciated that specific functions, and accordingly utilities, of GAM358 correlate with, and may be deduced from, the identity of the target genes which GAM358 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5164] Nucleotide sequences of the GAM358 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM358 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM358 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM358 are further described hereinbelow with reference to Table Table1.

[5165] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM358 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5166]

[5167] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 359 (GAM359) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5168] GAM359 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM359 was detected is described hereinabove

with reference to Figs. 2-8.

[5169] GAM359 gene, herein designated GAM GENE, and GAM359 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5170] GAM359 gene, herein designated GAM GENE, encodes a GAM359 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM359 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM359 precursor RNA is designated SEQ ID:5541, and is provided hereinbelow with reference to the sequence listing part.

[5171] GAM359 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM359 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5172] An enzyme complex designated DICER COMPLEX, dices the GAM359 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM359 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 22%) nucleotide sequence of GAM359 RNA is designated SEQ ID:5542, and is provided hereinbelow with reference to the sequence listing part.

[5173] GAM359 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM359 target RNA, herein designated GAM TARGET RNA. GAM359 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5174] GAM359 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM359 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM359 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM359 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM359 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5175] The complementary binding of GAM359 RNA, herein designated GAM RNA, to target binding sites on GAM359 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM359 target RNA, herein designated GAM TARGET RNA, into GAM359 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[5176] It is appreciated that GAM359 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM359 target genes. The mRNA of each one of this plurality of GAM359 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM359 RNA, herein designated GAM RNA, and which when bound by GAM359 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM359 target proteins.

[5177] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM359 gene, herein designated GAM GENE, on one or more GAM359 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5178] It is yet further appreciated that specific functions, and accordingly utilities, of GAM359 correlate with, and may be deduced from, the identity of the target genes which GAM359 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5179] Nucleotide sequences of the GAM359 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM359 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM359 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM359 are further described hereinbelow with reference to Table Table1.

[5180] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM359 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5181]

[5182] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 360 (GAM360) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5183] GAM360 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM360 was detected is described hereinabove with reference to Figs. 2-8.

[5184] GAM360 gene, herein designated GAM GENE, and GAM360 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5185] GAM360 gene, herein designated GAM GENE, encodes a GAM360 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM360 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM360 precursor RNA is designated SEQ ID:5556, and is provided hereinbelow with reference to the sequence listing part.

[5186] GAM360 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM360 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5187] An enzyme complex designated DICER COMPLEX, dices the GAM360 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM360 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM360 RNA is designated SEQ ID:5557, and is provided hereinbelow with reference to the sequence listing part.

[5188] GAM360 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM360 target RNA, herein designated GAM TARGET RNA.

GAM360 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5189] GAM360 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM360 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM360 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM360 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM360 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5190] The complementary binding of GAM360 RNA, herein designated GAM RNA, to target binding sites on GAM360 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM360 target RNA, herein designated GAM TARGET RNA, into GAM360 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5191] It is appreciated that GAM360 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM360 target genes. The mRNA of each one of this plurality of GAM360 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM360 RNA, herein designated GAM RNA, and which when bound by GAM360 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM360 target proteins.

[5192] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM360 gene, herein designated GAM GENE, on one or more GAM360 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5193] It is yet further appreciated that specific functions, and accordingly utilities, of GAM360 correlate with, and may be deduced from, the identity of the target genes which GAM360 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5194] Nucleotide sequences of the GAM360 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM360 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM360 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM360 are further described hereinbelow with reference to Table Table1.

[5195] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM360 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5196]

[5197] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 361 (GAM361) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5198] GAM361 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM361 was detected is described hereinabove with reference to Figs. 2-8.

[5199] GAM361 gene, herein designated GAM GENE, and GAM361 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5200] GAM361 gene, herein designated GAM GENE, encodes a

GAM361 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM361 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM361 precursor RNA is designated SEQ ID:5566, and is provided hereinbelow with reference to the sequence listing part.

[5201] GAM361 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM361 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5202] An enzyme complex designated DICER COMPLEX, dices the GAM361 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM361 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM361 RNA is designated SEQ ID:5567, and is provided hereinbelow with reference to the sequence listing part.

[5203] GAM361 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM361 target RNA, herein designated GAM TARGET RNA. GAM361 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5204] GAM361 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM361 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM361 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM361 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM361 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5205] The complementary binding of GAM361 RNA, herein designated GAM RNA, to target binding sites on GAM361 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM361 target RNA, herein designated GAM TARGET RNA, into GAM361 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5206] It is appreciated that GAM361 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM361 target genes. The mRNA of each one of this plurality of GAM361 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM361 RNA, herein designated GAM RNA, and which when bound by GAM361 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM361 target proteins.

[5207] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM361 gene, herein designated GAM GENE, on one or more GAM361 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5208] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM361 correlate with, and may be deduced from, the identity of the target genes which GAM361 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5209] Nucleotide sequences of the GAM361 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM361 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM361 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM361 are further described hereinbelow with reference to Table Table1.

[5210] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM361 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5211]

[5212] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 362 (GAM362) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[5213] GAM362 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM362 was detected is described hereinabove with reference to Figs. 2-8.

[5214] GAM362 gene, herein designated GAM GENE, and GAM362 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5215] GAM362 gene, herein designated GAM GENE, encodes a GAM362 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM362 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM362 precursor RNA is designated SEQ ID:5577, and is provided hereinbelow with reference to the sequence listing part.

[5216] GAM362 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM362 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5217] An enzyme complex designated DICER COMPLEX, dices the GAM362 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM362 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM362 RNA is designated SEQ ID:5578, and is provided hereinbelow with reference to the sequence listing part.

[5218] GAM362 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM362 target RNA, herein designated GAM TARGET RNA.
GAM362 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5219] GAM362 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM362 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM362 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM362 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM362 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5220] The complementary binding of GAM362 RNA, herein designated GAM RNA, to target binding sites on GAM362 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM362 target RNA, herein designated GAM TARGET RNA, into GAM362 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5221] It is appreciated that GAM362 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM362 target genes. The mRNA of each one of this plurality of GAM362 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM362 RNA, herein designated GAM RNA, and which when bound by GAM362 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM362 target proteins.

[5222] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM362 gene, herein designated GAM GENE, on one or more GAM362 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5223] It is yet further appreciated that specific functions, and accordingly utilities, of GAM362 correlate with, and may be deduced from, the identity of the target genes which GAM362 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5224] Nucleotide sequences of the GAM362 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM362 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM362 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM362 are further described hereinbelow with reference to Table Table1.

[5225] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM362 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5226]

[5227] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 363 (GAM363) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5228] GAM363 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM363 was detected is described hereinabove with reference to Figs. 2-8.

[5229] GAM363 gene, herein designated GAM GENE, and GAM363 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5230] GAM363 gene, herein designated GAM GENE, encodes a GAM363 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM363 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM363 precursor RNA is designated SEQ ID:5609, and is provided hereinbelow with reference to the sequence listing part.

[5231] GAM363 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM363 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5232] An enzyme complex designated DICER COMPLEX, dices the GAM363 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM363 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM363 RNA is designated SEQ ID:5610, and is provided

hereinbelow with reference to the sequence listing part.

[5233] GAM363 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM363 target RNA, herein designated GAM TARGET RNA.

GAM363 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5234] GAM363 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM363 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM363 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM363 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM363 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5235] The complementary binding of GAM363 RNA, herein designated GAM RNA, to target binding sites on GAM363 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM363 target RNA, herein designated GAM TARGET RNA, into GAM363 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5236] It is appreciated that GAM363 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM363 target genes. The mRNA of each one of this plurality of GAM363 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM363 RNA, herein designated GAM RNA, and which when bound by GAM363 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM363 tar-

get proteins.

[5237] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM363 gene, herein designated GAM GENE, on one or more GAM363 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5238] It is yet further appreciated that specific functions, and accordingly utilities, of GAM363 correlate with, and may be deduced from, the identity of the target genes which GAM363 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5239] Nucleotide sequences of the GAM363 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM363 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM363 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM363 are further described hereinbelow with reference to Table Table1.

[5240] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM363 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5241]

[5242] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 364 (GAM364) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5243] GAM364 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM364 was detected is described hereinabove with reference to Figs. 2-8.

[5244] GAM364 gene, herein designated GAM GENE, and GAM364 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5245] GAM364 gene, herein designated GAM GENE, encodes a GAM364 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM364 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM364 precursor RNA is designated SEQ ID:5617, and is provided hereinbelow with reference to the sequence listing part.

[5246] GAM364 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM364 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5247] An enzyme complex designated DICER COMPLEX, dices

the GAM364 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM364 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM364 RNA is designated SEQ ID:5618, and is provided hereinbelow with reference to the sequence listing part.

[5248] GAM364 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM364 target RNA, herein designated GAM TARGET RNA. GAM364 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5249] GAM364 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM364 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM364

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM364 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM364 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5250] The complementary binding of GAM364 RNA, herein designated GAM RNA, to target binding sites on GAM364 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM364 target RNA, herein designated GAM TARGET RNA, into GAM364 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5251] It is appreciated that GAM364 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM364 target genes. The mRNA of each one of this plurality of GAM364 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM364 RNA, herein designated GAM RNA, and which when bound by GAM364 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM364 target proteins.

[5252] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM364 gene, herein designated GAM GENE, on one or more GAM364 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5253] It is yet further appreciated that specific functions, and accordingly utilities, of GAM364 correlate with, and may be deduced from, the identity of the target genes which GAM364 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5254] Nucleotide sequences of the GAM364 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM364 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM364 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM364 are further described hereinbelow with reference to Table Table1.

[5255] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM364 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5256]

[5257] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 365 (GAM365) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5258] GAM365 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM365 was detected is described hereinabove with reference to Figs. 2-8.

[5259] GAM365 gene, herein designated GAM GENE, and GAM365 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5260] GAM365 gene, herein designated GAM GENE, encodes a GAM365 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM365 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM365 precursor RNA is designated SEQ ID:5631, and is provided hereinbelow with reference to the sequence listing part.

[5261] GAM365 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM365 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5262] An enzyme complex designated DICER COMPLEX, dices the GAM365 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM365 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM365 RNA is designated SEQ ID:5632, and is provided hereinbelow with reference to the sequence listing part.

[5263] GAM365 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM365 target RNA, herein designated GAM TARGET RNA. GAM365 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5264] GAM365 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM365 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM365 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM365 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM365 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[5265] The complementary binding of GAM365 RNA, herein designated GAM RNA, to target binding sites on GAM365 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM365 target RNA, herein designated GAM TARGET RNA, into GAM365 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5266] It is appreciated that GAM365 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM365 target genes. The mRNA of each one of this plurality of GAM365 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM365 RNA, herein designated GAM RNA, and which when bound by GAM365 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM365 target proteins.

[5267] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM365 gene, herein designated GAM GENE, on one or

more GAM365 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5268] It is yet further appreciated that specific functions, and accordingly utilities, of GAM365 correlate with, and may be deduced from, the identity of the target genes which GAM365 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5269] Nucleotide sequences of the GAM365 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM365 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM365 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM365 are further de-

scribed hereinbelow with reference to Table Table1.

[5270] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM365 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5271]

[5272] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 366 (GAM366) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5273] GAM366 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM366 was detected is described hereinabove with reference to Figs. 2-8.

[5274] GAM366 gene, herein designated GAM GENE, and GAM366 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5275] GAM366 gene, herein designated GAM GENE, encodes a GAM366 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM366 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM366 precursor RNA is designated SEQ ID:5639, and is provided hereinbelow with reference to the sequence listing part.

[5276] GAM366 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM366 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5277] An enzyme complex designated DICER COMPLEX, dices the GAM366 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM366 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 76%) nucleotide sequence of GAM366 RNA is designated SEQ ID:5640, and is provided hereinbelow with reference to the sequence listing part.

[5278] GAM366 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM366 target RNA, herein designated GAM TARGET RNA. GAM366 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5279] GAM366 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM366 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM366 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM366 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM366 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5280] The complementary binding of GAM366 RNA, herein designated GAM RNA, to target binding sites on GAM366 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM366 target RNA, herein designated GAM TARGET RNA, into GAM366 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5281] It is appreciated that GAM366 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM366 target genes. The mRNA of each one of this plurality of GAM366 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM366 RNA, herein designated GAM RNA, and which when bound by GAM366 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM366 target proteins.

[5282] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM366 gene, herein designated GAM GENE, on one or more GAM366 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5283] It is yet further appreciated that specific functions, and accordingly utilities, of GAM366 correlate with, and may

be deduced from, the identity of the target genes which GAM366 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5284] Nucleotide sequences of the GAM366 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM366 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM366 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM366 are further described hereinbelow with reference to Table Table1.

[5285] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM366 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5286]

[5287] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 367 (GAM367) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5288] GAM367 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM367 was detected is described hereinabove with reference to Figs. 2-8.

[5289] GAM367 gene, herein designated GAM GENE, and GAM367 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5290] GAM367 gene, herein designated GAM GENE, encodes a GAM367 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM367 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM367 precursor RNA is designated SEQ ID:5660, and is provided hereinbelow with reference to the sequence listing part.

[5291] GAM367 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM367 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5292] An enzyme complex designated DICER COMPLEX, dices the GAM367 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM367 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM367 RNA is designated SEQ ID:5661, and is provided hereinbelow with reference to the sequence listing part.

[5293] GAM367 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM367 target RNA, herein designated GAM TARGET RNA. GAM367 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5294] GAM367 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM367 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM367 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM367 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM367 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5295] The complementary binding of GAM367 RNA, herein designated GAM RNA, to target binding sites on GAM367 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM367 target RNA, herein designated GAM TARGET RNA, into GAM367 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5296] It is appreciated that GAM367 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM367 target genes. The mRNA of each one of this plurality of GAM367 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM367 RNA, herein designated GAM RNA, and which when bound by GAM367 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM367 target proteins.

[5297] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM367 gene, herein designated GAM GENE, on one or more GAM367 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5298] It is yet further appreciated that specific functions, and accordingly utilities, of GAM367 correlate with, and may be deduced from, the identity of the target genes which GAM367 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5299] Nucleotide sequences of the GAM367 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM367 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM367 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM367 are further described hereinbelow with reference to Table Table1.

[5300] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM367 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5301]

[5302] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 368 (GAM368) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5303] GAM368 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM368 was detected is described hereinabove with reference to Figs. 2-8.

[5304] GAM368 gene, herein designated GAM GENE, and GAM368 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5305] GAM368 gene, herein designated GAM GENE, encodes a GAM368 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM368 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM368 precursor RNA is desig-

nated SEQ ID:5676, and is provided hereinbelow with reference to the sequence listing part.

[5306] GAM368 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM368 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5307] An enzyme complex designated DICER COMPLEX, dices the GAM368 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM368 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM368 RNA is designated SEQ ID:5677, and is provided hereinbelow with reference to the sequence listing part.

[5308] GAM368 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM368 target RNA, herein designated GAM TARGET RNA. GAM368 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5309] GAM368 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM368 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM368 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM368 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM368

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5310] The complementary binding of GAM368 RNA, herein designated GAM RNA, to target binding sites on GAM368 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM368 target RNA, herein designated GAM TARGET RNA, into GAM368 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5311] It is appreciated that GAM368 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM368 target genes. The mRNA of each one of this plurality of GAM368 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM368 RNA, herein designated GAM RNA, and which when bound by GAM368 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM368 target proteins.

[5312] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM368 gene, herein designated GAM GENE, on one or more GAM368 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5313] It is yet further appreciated that specific functions, and accordingly utilities, of GAM368 correlate with, and may be deduced from, the identity of the target genes which GAM368 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5314] Nucleotide sequences of the GAM368 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM368 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM368 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM368 are further described hereinbelow with reference to Table Table1.

[5315] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM368 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5316]

[5317] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 369 (GAM369) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5318] GAM369 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM369 was detected is described hereinabove with reference to Figs. 2-8.

[5319] GAM369 gene, herein designated GAM GENE, and

GAM369 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5320] GAM369 gene, herein designated GAM GENE, encodes a GAM369 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM369 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM369 precursor RNA is designated SEQ ID:5703, and is provided hereinbelow with reference to the sequence listing part.

[5321] GAM369 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM369 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5322] An enzyme complex designated DICER COMPLEX, dices the GAM369 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM369 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM369 RNA is designated SEQ ID:5704, and is provided hereinbelow with reference to the sequence listing part.

[5323] GAM369 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM369 target RNA, herein designated GAM TARGET RNA. GAM369 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5324] GAM369 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM369 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM369 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM369 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM369 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5325] The complementary binding of GAM369 RNA, herein designated GAM RNA, to target binding sites on GAM369 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM369 target RNA, herein designated GAM TARGET RNA, into GAM369 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5326] It is appreciated that GAM369 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM369 target genes. The mRNA of each one of this plurality of GAM369 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM369 RNA, herein designated GAM RNA, and which when bound by GAM369 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM369 target proteins.

[5327] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM369 gene, herein designated GAM GENE, on one or more GAM369 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5328] It is yet further appreciated that specific functions, and accordingly utilities, of GAM369 correlate with, and may be deduced from, the identity of the target genes which GAM369 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5329] Nucleotide sequences of the GAM369 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM369 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM369 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM369 are further described hereinbelow with reference to Table Table1.

[5330] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM369 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5331]

[5332] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 370 (GAM370) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5333] GAM370 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM370 was detected is described hereinabove with reference to Figs. 2-8.

[5334] GAM370 gene, herein designated GAM GENE, and GAM370 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5335] GAM370 gene, herein designated GAM GENE, encodes a GAM370 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM370 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM370 precursor RNA is designated SEQ ID:5719, and is provided hereinbelow with reference to the sequence listing part.

[5336] GAM370 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM370 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5337] An enzyme complex designated DICER COMPLEX, dices the GAM370 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM370 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 27%) nucleotide sequence of GAM370 RNA is designated SEQ ID:5720, and is provided hereinbelow with reference to the sequence listing part.

[5338] GAM370 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM370 target RNA, herein designated GAM TARGET RNA. GAM370 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5339] GAM370 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM370 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM370 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM370 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM370 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5340] The complementary binding of GAM370 RNA, herein designated GAM RNA, to target binding sites on GAM370 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM370 target RNA, herein designated GAM TARGET RNA, into GAM370 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5341] It is appreciated that GAM370 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM370 target genes. The mRNA of each one of this plurality of GAM370 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM370 RNA, herein designated GAM RNA, and which when bound by GAM370 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM370 target proteins.

[5342] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM370 gene, herein designated GAM GENE, on one or more GAM370 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5343] It is yet further appreciated that specific functions, and accordingly utilities, of GAM370 correlate with, and may be deduced from, the identity of the target genes which GAM370 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5344] Nucleotide sequences of the GAM370 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM370 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM370 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM370 are further described hereinbelow with reference to Table Table1.

[5345] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM370 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5346]

[5347] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 371 (GAM371) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5348] GAM371 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM371 was detected is described hereinabove with reference to Figs. 2-8.

[5349] GAM371 gene, herein designated GAM GENE, and GAM371 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5350] GAM371 gene, herein designated GAM GENE, encodes a GAM371 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM371 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM371 precursor RNA is designated SEQ ID:5729, and is provided hereinbelow with reference to the sequence listing part.

[5351] GAM371 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM371 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5352] An enzyme complex designated DICER COMPLEX, dices the GAM371 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM371 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM371 RNA is designated SEQ ID:5730, and is provided hereinbelow with reference to the sequence listing part.

[5353] GAM371 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM371 target RNA, herein designated GAM TARGET RNA. GAM371 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5354] GAM371 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM371 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM371 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM371 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM371 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5355] The complementary binding of GAM371 RNA, herein designated GAM RNA, to target binding sites on GAM371 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM371 target RNA, herein designated GAM TARGET RNA, into GAM371 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5356] It is appreciated that GAM371 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM371 target genes. The mRNA of each one of this plurality of GAM371 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM371 RNA,

herein designated GAM RNA, and which when bound by GAM371 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM371 target proteins.

[5357] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM371 gene, herein designated GAM GENE, on one or more GAM371 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5358] It is yet further appreciated that specific functions, and accordingly utilities, of GAM371 correlate with, and may be deduced from, the identity of the target genes which

GAM371 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5359] Nucleotide sequences of the GAM371 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM371 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM371 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM371 are further described hereinbelow with reference to Table Table1.

[5360] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM371 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5361]

[5362] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 372 (GAM372) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5363] GAM372 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM372 was detected is described hereinabove with reference to Figs. 2-8.

[5364] GAM372 gene, herein designated GAM GENE, and GAM372 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5365] GAM372 gene, herein designated GAM GENE, encodes a GAM372 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM372 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM372 precursor RNA is designated SEQ ID:5747, and is provided hereinbelow with reference to the sequence listing part.

[5366] GAM372 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM372 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[5367] An enzyme complex designated DICER COMPLEX, dices the GAM372 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM372 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM372 RNA is designated SEQ ID:5748, and is provided hereinbelow with reference to the sequence listing part.

[5368] GAM372 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM372 target RNA, herein designated GAM TARGET RNA.
GAM372 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5369] GAM372 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM372 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM372 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM372 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM372 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5370] The complementary binding of GAM372 RNA, herein designated GAM RNA, to target binding sites on GAM372 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM372 target RNA, herein desig-

nated GAM TARGET RNA, into GAM372 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5371] It is appreciated that GAM372 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM372 target genes. The mRNA of each one of this plurality of GAM372 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM372 RNA, herein designated GAM RNA, and which when bound by GAM372 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM372 target proteins.

[5372] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM372 gene, herein designated GAM GENE, on one or more GAM372 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5373] It is yet further appreciated that specific functions, and accordingly utilities, of GAM372 correlate with, and may be deduced from, the identity of the target genes which GAM372 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5374] Nucleotide sequences of the GAM372 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM372 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM372 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM372 are further described hereinbelow with reference to Table Table1.

[5375] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM372 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[5376]

[5377] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 373 (GAM373) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5378] GAM373 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM373 was detected is described hereinabove with reference to Figs. 2-8.

[5379] GAM373 gene, herein designated GAM GENE, and GAM373 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5380] GAM373 gene, herein designated GAM GENE, encodes a GAM373 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM373 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM373 precursor RNA is designated SEQ ID:5765, and is provided hereinbelow with ref-

erence to the sequence listing part.

[5381] GAM373 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM373 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5382] An enzyme complex designated DICER COMPLEX, dices the GAM373 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM373 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM373 RNA is designated SEQ ID:5766, and is provided hereinbelow with reference to the sequence listing part.

[5383] GAM373 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM373 target RNA, herein designated GAM TARGET RNA.

GAM373 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5384] GAM373 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM373 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM373 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM373 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM373 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5385] The complementary binding of GAM373 RNA, herein designated GAM RNA, to target binding sites on GAM373 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM373 target RNA, herein designated GAM TARGET RNA, into GAM373 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5386] It is appreciated that GAM373 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM373 target genes. The mRNA of each one of this plurality of GAM373 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM373 RNA, herein designated GAM RNA, and which when bound by GAM373 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM373 target proteins.

[5387] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM373 gene, herein designated GAM GENE, on one or more GAM373 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5388] It is yet further appreciated that specific functions, and accordingly utilities, of GAM373 correlate with, and may be deduced from, the identity of the target genes which GAM373 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5389] Nucleotide sequences of the GAM373 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM373 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM373 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM373 are further described hereinbelow with reference to Table Table1.

[5390] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM373 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5391]

[5392] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 374 (GAM374) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5393] GAM374 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM374 was detected is described hereinabove with reference to Figs. 2-8.

[5394] GAM374 gene, herein designated GAM GENE, and GAM374 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[5395] GAM374 gene, herein designated GAM GENE, encodes a GAM374 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM374 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM374 precursor RNA is designated SEQ ID:5800, and is provided hereinbelow with reference to the sequence listing part.

[5396] GAM374 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM374 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5397] An enzyme complex designated DICER COMPLEX, dices the GAM374 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM374 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM374 RNA is designated SEQ ID:5801, and is provided hereinbelow with reference to the sequence listing part.

[5398] GAM374 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM374 target RNA, herein designated GAM TARGET RNA. GAM374 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5399] GAM374 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM374 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM374 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM374 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM374 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5400] The complementary binding of GAM374 RNA, herein designated GAM RNA, to target binding sites on GAM374 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM374 target RNA, herein designated GAM TARGET RNA, into GAM374 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5401] It is appreciated that GAM374 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM374 target genes. The mRNA of each one of this plurality of GAM374 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM374 RNA, herein designated GAM RNA, and which when bound by GAM374 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM374 target proteins.

[5402] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM374 gene, herein designated GAM GENE, on one or more GAM374 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[5403] It is yet further appreciated that specific functions, and accordingly utilities, of GAM374 correlate with, and may be deduced from, the identity of the target genes which GAM374 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5404] Nucleotide sequences of the GAM374 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM374 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM374 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM374 are further described hereinbelow with reference to Table Table1.

[5405] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM374 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5406]

[5407] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

375 (GAM375) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5408] GAM375 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM375 was detected is described hereinabove with reference to Figs. 2-8.

[5409] GAM375 gene, herein designated GAM GENE, and GAM375 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5410] GAM375 gene, herein designated GAM GENE, encodes a GAM375 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM375 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM375 precursor RNA is designated SEQ ID:5813, and is provided hereinbelow with reference to the sequence listing part.

[5411] GAM375 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM375 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5412] An enzyme complex designated DICER COMPLEX, dices the GAM375 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM375 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM375 RNA is designated SEQ ID:5814, and is provided hereinbelow with reference to the sequence listing part.

[5413] GAM375 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM375 target RNA, herein designated GAM TARGET RNA. GAM375 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5414] GAM375 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM375 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM375 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM375 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM375 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5415] The complementary binding of GAM375 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM375 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM375 target RNA, herein designated GAM TARGET RNA, into GAM375 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5416] It is appreciated that GAM375 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM375 target genes. The mRNA of each one of this plurality of GAM375 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM375 RNA, herein designated GAM RNA, and which when bound by GAM375 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM375 target proteins.

[5417] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM375 gene, herein designated GAM GENE, on one or more GAM375 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5418] It is yet further appreciated that specific functions, and accordingly utilities, of GAM375 correlate with, and may be deduced from, the identity of the target genes which GAM375 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5419] Nucleotide sequences of the GAM375 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM375 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM375 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM375 are further described hereinbelow with reference to Table Table1.

[5420] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM375 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5421]

[5422] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 376 (GAM376) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5423] GAM376 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM376 was detected is described hereinabove with reference to Figs. 2-8.

[5424] GAM376 gene, herein designated GAM GENE, and GAM376 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5425] GAM376 gene, herein designated GAM GENE, encodes a GAM376 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM376 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM376 precursor RNA is designated SEQ ID:5837, and is provided hereinbelow with reference to the sequence listing part.

[5426] GAM376 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM376 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5427] An enzyme complex designated DICER COMPLEX, dices the GAM376 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM376 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 68%) nucleotide sequence of GAM376 RNA is designated SEQ ID:5838, and is provided hereinbelow with reference to the sequence listing part.

[5428] GAM376 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM376 target RNA, herein designated GAM TARGET RNA. GAM376 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5429] GAM376 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM376 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM376 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM376 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM376 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5430] The complementary binding of GAM376 RNA, herein designated GAM RNA, to target binding sites on GAM376 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM376 target RNA, herein designated GAM TARGET RNA, into GAM376 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5431] It is appreciated that GAM376 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM376 target genes. The mRNA of each one of this plurality of GAM376 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM376 RNA, herein designated GAM RNA, and which when bound by

GAM376 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM376 target proteins.

[5432] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM376 gene, herein designated GAM GENE, on one or more GAM376 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5433] It is yet further appreciated that specific functions, and accordingly utilities, of GAM376 correlate with, and may be deduced from, the identity of the target genes which GAM376 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[5434] Nucleotide sequences of the GAM376 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM376 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM376 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM376 are further described hereinbelow with reference to Table Table1.

[5435] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM376 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5436]

[5437] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 377 (GAM377) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5438] GAM377 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM377 was detected is described hereinabove with reference to Figs. 2-8.

[5439] GAM377 gene, herein designated GAM GENE, and GAM377 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5440] GAM377 gene, herein designated GAM GENE, encodes a GAM377 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM377 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM377 precursor RNA is designated SEQ ID:5849, and is provided hereinbelow with reference to the sequence listing part.

[5441] GAM377 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM377 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[5442] An enzyme complex designated DICER COMPLEX, dices the GAM377 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM377 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 40%) nucleotide sequence of GAM377 RNA is designated SEQ ID:5850, and is provided hereinbelow with reference to the sequence listing part.

[5443] GAM377 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM377 target RNA, herein designated GAM TARGET RNA. GAM377 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5444] GAM377 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM377 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM377 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM377 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM377 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5445] The complementary binding of GAM377 RNA, herein designated GAM RNA, to target binding sites on GAM377 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM377 target RNA, herein designated GAM TARGET RNA, into GAM377 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5446] It is appreciated that GAM377 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM377 target genes. The mRNA of each one of this plurality of GAM377 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM377 RNA, herein designated GAM RNA, and which when bound by GAM377 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM377 target proteins.

[5447] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM377 gene, herein designated GAM GENE, on one or more GAM377 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5448] It is yet further appreciated that specific functions, and accordingly utilities, of GAM377 correlate with, and may be deduced from, the identity of the target genes which GAM377 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5449] Nucleotide sequences of the GAM377 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM377 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM377 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM377 are further described hereinbelow with reference to Table Table1.

[5450] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM377 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5451]

[5452] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 378 (GAM378) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5453] GAM378 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM378 was detected is described hereinabove with reference to Figs. 2-8.

[5454] GAM378 gene, herein designated GAM GENE, and GAM378 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5455] GAM378 gene, herein designated GAM GENE, encodes a GAM378 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM378 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM378 precursor RNA is designated SEQ ID:5853, and is provided hereinbelow with reference to the sequence listing part.

[5456] GAM378 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM378 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5457] An enzyme complex designated DICER COMPLEX, dices the GAM378 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM378 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM378 RNA is designated SEQ ID:5854, and is provided hereinbelow with reference to the sequence listing part.

[5458] GAM378 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM378

target RNA, herein designated GAM TARGET RNA.

GAM378 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5459] GAM378 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM378 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM378 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM378 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM378 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5460] The complementary binding of GAM378 RNA, herein designated GAM RNA, to target binding sites on GAM378 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM378 target RNA, herein designated GAM TARGET RNA, into GAM378 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5461] It is appreciated that GAM378 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM378 target genes. The mRNA of each one of this plurality of GAM378 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM378 RNA, herein designated GAM RNA, and which when bound by GAM378 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM378 target proteins.

[5462] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM378 gene, herein designated GAM GENE, on one or more GAM378 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5463] It is yet further appreciated that specific functions, and accordingly utilities, of GAM378 correlate with, and may be deduced from, the identity of the target genes which GAM378 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5464] Nucleotide sequences of the GAM378 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM378 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM378 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM378 are further described hereinbelow with reference to Table Table1.

[5465] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM378 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5466]

[5467] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 379 (GAM379) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5468] GAM379 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM379 was detected is described hereinabove with reference to Figs. 2-8.

[5469] GAM379 gene, herein designated GAM GENE, and GAM379 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5470] GAM379 gene, herein designated GAM GENE, encodes a GAM379 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM379 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM379 precursor RNA is designated SEQ ID:5876, and is provided hereinbelow with reference to the sequence listing part.

[5471] GAM379 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM379 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5472] An enzyme complex designated DICER COMPLEX, dices the GAM379 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM379 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM379 RNA is designated SEQ ID:2525, and is provided hereinbelow with reference to the sequence listing part.

[5473] GAM379 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM379 target RNA, herein designated GAM TARGET RNA. GAM379 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5474] GAM379 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM379 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM379 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM379 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM379 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5475] The complementary binding of GAM379 RNA, herein designated GAM RNA, to target binding sites on GAM379 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM379 target RNA, herein designated GAM TARGET RNA, into GAM379 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5476] It is appreciated that GAM379 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM379 target genes. The mRNA of each one of this plu-

rality of GAM379 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM379 RNA, herein designated GAM RNA, and which when bound by GAM379 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM379 target proteins.

[5477] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM379 gene, herein designated GAM GENE, on one or more GAM379 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5478] It is yet further appreciated that specific functions, and accordingly utilities, of GAM379 correlate with, and may be deduced from, the identity of the target genes which GAM379 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5479] Nucleotide sequences of the GAM379 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM379 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM379 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM379 are further described hereinbelow with reference to Table Table1.

[5480] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM379 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5481]

[5482] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 380 (GAM380) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[5483] GAM380 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM380 was detected is described hereinabove with reference to Figs. 2-8.

[5484] GAM380 gene, herein designated GAM GENE, and GAM380 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5485] GAM380 gene, herein designated GAM GENE, encodes a GAM380 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM380 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM380 precursor RNA is designated SEQ ID:5879, and is provided hereinbelow with reference to the sequence listing part.

[5486] GAM380 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM380 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5487] An enzyme complex designated DICER COMPLEX, dices the GAM380 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM380 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 26%) nucleotide sequence of GAM380 RNA is designated SEQ ID:5880, and is provided hereinbelow with reference to the sequence listing part.

[5488] GAM380 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM380 target RNA, herein designated GAM TARGET RNA.
GAM380 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[5489] GAM380 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM380 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM380 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM380 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM380 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5490] The complementary binding of GAM380 RNA, herein designated GAM RNA, to target binding sites on GAM380 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM380 target RNA, herein designated GAM TARGET RNA, into GAM380 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5491] It is appreciated that GAM380 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM380 target genes. The mRNA of each one of this plurality of GAM380 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM380 RNA, herein designated GAM RNA, and which when bound by GAM380 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM380 target proteins.

[5492] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM380 gene, herein designated GAM GENE, on one or more GAM380 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5493] It is yet further appreciated that specific functions, and accordingly utilities, of GAM380 correlate with, and may be deduced from, the identity of the target genes which GAM380 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5494] Nucleotide sequences of the GAM380 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM380 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM380 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM380 are further described hereinbelow with reference to Table Table1.

[5495] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM380 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5496]

[5497] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 381 (GAM381) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5498] GAM381 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM381 was detected is described hereinabove with reference to Figs. 2-8.

[5499] GAM381 gene, herein designated GAM GENE, and GAM381 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5500] GAM381 gene, herein designated GAM GENE, encodes a GAM381 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM381 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM381 precursor RNA is designated SEQ ID:5892, and is provided hereinbelow with reference to the sequence listing part.

[5501] GAM381 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM381 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5502] An enzyme complex designated DICER COMPLEX, dices the GAM381 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM381 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of

GAM381 RNA is designated SEQ ID:5893, and is provided hereinbelow with reference to the sequence listing part.

[5503] GAM381 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM381 target RNA, herein designated GAM TARGET RNA. GAM381 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5504] GAM381 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM381 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM381 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM381 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM381 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5505] The complementary binding of GAM381 RNA, herein designated GAM RNA, to target binding sites on GAM381 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM381 target RNA, herein designated GAM TARGET RNA, into GAM381 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5506] It is appreciated that GAM381 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM381 target genes. The mRNA of each one of this plurality of GAM381 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM381 RNA, herein designated GAM RNA, and which when bound by GAM381 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM381 target proteins.

[5507] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM381 gene, herein designated GAM GENE, on one or more GAM381 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5508] It is yet further appreciated that specific functions, and accordingly utilities, of GAM381 correlate with, and may be deduced from, the identity of the target genes which GAM381 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5509] Nucleotide sequences of the GAM381 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM381 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM381 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM381 are further described hereinbelow with reference to Table Table1.

[5510] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM381 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5511]

[5512] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 382 (GAM382) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5513] GAM382 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM382 was detected is described hereinabove

with reference to Figs. 2-8.

[5514] GAM382 gene, herein designated GAM GENE, and GAM382 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5515] GAM382 gene, herein designated GAM GENE, encodes a GAM382 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM382 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM382 precursor RNA is designated SEQ ID:5913, and is provided hereinbelow with reference to the sequence listing part.

[5516] GAM382 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM382 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5517] An enzyme complex designated DICER COMPLEX, dices the GAM382 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM382 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM382 RNA is designated SEQ ID:5914, and is provided hereinbelow with reference to the sequence listing part.

[5518] GAM382 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM382 target RNA, herein designated GAM TARGET RNA. GAM382 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5519] GAM382 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM382 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM382 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM382 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM382 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5520] The complementary binding of GAM382 RNA, herein designated GAM RNA, to target binding sites on GAM382 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM382 target RNA, herein designated GAM TARGET RNA, into GAM382 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[5521] It is appreciated that GAM382 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM382 target genes. The mRNA of each one of this plurality of GAM382 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM382 RNA, herein designated GAM RNA, and which when bound by GAM382 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM382 target proteins.

[5522] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM382 gene, herein designated GAM GENE, on one or more GAM382 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5523] It is yet further appreciated that specific functions, and accordingly utilities, of GAM382 correlate with, and may be deduced from, the identity of the target genes which GAM382 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5524] Nucleotide sequences of the GAM382 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM382 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM382 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM382 are further described hereinbelow with reference to Table Table1.

[5525] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM382 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5526]

[5527] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 383 (GAM383) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5528] GAM383 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM383 was detected is described hereinabove with reference to Figs. 2-8.

[5529] GAM383 gene, herein designated GAM GENE, and GAM383 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5530] GAM383 gene, herein designated GAM GENE, encodes a GAM383 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM383 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM383 precursor RNA is designated SEQ ID:5924, and is provided hereinbelow with reference to the sequence listing part.

[5531] GAM383 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM383 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5532] An enzyme complex designated DICER COMPLEX, dices the GAM383 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM383 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM383 RNA is designated SEQ ID:5925, and is provided hereinbelow with reference to the sequence listing part.

[5533] GAM383 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM383 target RNA, herein designated GAM TARGET RNA.

GAM383 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5534] GAM383 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM383 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM383 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM383 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM383 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5535] The complementary binding of GAM383 RNA, herein designated GAM RNA, to target binding sites on GAM383 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM383 target RNA, herein designated GAM TARGET RNA, into GAM383 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5536] It is appreciated that GAM383 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM383 target genes. The mRNA of each one of this plurality of GAM383 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM383 RNA, herein designated GAM RNA, and which when bound by GAM383 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM383 target proteins.

[5537] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM383 gene, herein designated GAM GENE, on one or more GAM383 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5538] It is yet further appreciated that specific functions, and accordingly utilities, of GAM383 correlate with, and may be deduced from, the identity of the target genes which GAM383 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5539] Nucleotide sequences of the GAM383 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM383 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM383 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM383 are further described hereinbelow with reference to Table Table1.

[5540] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM383 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5541]

[5542] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 384 (GAM384) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5543] GAM384 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM384 was detected is described hereinabove with reference to Figs. 2-8.

[5544] GAM384 gene, herein designated GAM GENE, and GAM384 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5545] GAM384 gene, herein designated GAM GENE, encodes a

GAM384 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM384 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM384 precursor RNA is designated SEQ ID:5945, and is provided hereinbelow with reference to the sequence listing part.

[5546] GAM384 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM384 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5547] An enzyme complex designated DICER COMPLEX, dices the GAM384 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM384 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 40%) nucleotide sequence of GAM384 RNA is designated SEQ ID:5946, and is provided hereinbelow with reference to the sequence listing part.

[5548] GAM384 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM384 target RNA, herein designated GAM TARGET RNA. GAM384 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5549] GAM384 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM384 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM384 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM384 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM384 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5550] The complementary binding of GAM384 RNA, herein designated GAM RNA, to target binding sites on GAM384 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM384 target RNA, herein designated GAM TARGET RNA, into GAM384 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5551] It is appreciated that GAM384 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM384 target genes. The mRNA of each one of this plurality of GAM384 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM384 RNA, herein designated GAM RNA, and which when bound by GAM384 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM384 target proteins.

[5552] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM384 gene, herein designated GAM GENE, on one or more GAM384 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5553] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM384 correlate with, and may be deduced from, the identity of the target genes which GAM384 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5554] Nucleotide sequences of the GAM384 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM384 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM384 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM384 are further described hereinbelow with reference to Table Table1.

[5555] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM384 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5556]

[5557] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 385 (GAM385) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[5558] GAM385 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM385 was detected is described hereinabove with reference to Figs. 2-8.

[5559] GAM385 gene, herein designated GAM GENE, and GAM385 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5560] GAM385 gene, herein designated GAM GENE, encodes a GAM385 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM385 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM385 precursor RNA is designated SEQ ID:5969, and is provided hereinbelow with reference to the sequence listing part.

[5561] GAM385 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM385 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5562] An enzyme complex designated DICER COMPLEX, dices the GAM385 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM385 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM385 RNA is designated SEQ ID:5970, and is provided hereinbelow with reference to the sequence listing part.

[5563] GAM385 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM385 target RNA, herein designated GAM TARGET RNA. GAM385 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5564] GAM385 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM385 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM385 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM385 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM385 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5565] The complementary binding of GAM385 RNA, herein designated GAM RNA, to target binding sites on GAM385 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM385 target RNA, herein designated GAM TARGET RNA, into GAM385 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5566] It is appreciated that GAM385 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM385 target genes. The mRNA of each one of this plurality of GAM385 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM385 RNA, herein designated GAM RNA, and which when bound by GAM385 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM385 target proteins.

[5567] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM385 gene, herein designated GAM GENE, on one or more GAM385 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5568] It is yet further appreciated that specific functions, and accordingly utilities, of GAM385 correlate with, and may be deduced from, the identity of the target genes which GAM385 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5569] Nucleotide sequences of the GAM385 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM385 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM385 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM385 are further described hereinbelow with reference to Table Table1.

[5570] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM385 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5571]

[5572] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 386 (GAM386) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5573] GAM386 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM386 was detected is described hereinabove with reference to Figs. 2-8.

[5574] GAM386 gene, herein designated GAM GENE, and GAM386 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5575] GAM386 gene, herein designated GAM GENE, encodes a GAM386 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM386 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM386 precursor RNA is designated SEQ ID:5975, and is provided hereinbelow with reference to the sequence listing part.

[5576] GAM386 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM386 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5577] An enzyme complex designated DICER COMPLEX, dices the GAM386 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM386 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM386 RNA is designated SEQ ID:5976, and is provided

hereinbelow with reference to the sequence listing part.

[5578] GAM386 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM386 target RNA, herein designated GAM TARGET RNA.

GAM386 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5579] GAM386 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM386 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM386 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM386 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM386 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5580] The complementary binding of GAM386 RNA, herein designated GAM RNA, to target binding sites on GAM386 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM386 target RNA, herein designated GAM TARGET RNA, into GAM386 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5581] It is appreciated that GAM386 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM386 target genes. The mRNA of each one of this plurality of GAM386 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM386 RNA, herein designated GAM RNA, and which when bound by GAM386 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM386 tar-

get proteins.

[5582] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM386 gene, herein designated GAM GENE, on one or more GAM386 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5583] It is yet further appreciated that specific functions, and accordingly utilities, of GAM386 correlate with, and may be deduced from, the identity of the target genes which GAM386 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5584] Nucleotide sequences of the GAM386 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM386 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM386 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM386 are further described hereinbelow with reference to Table Table1.

[5585] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM386 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5586]

[5587] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 387 (GAM387) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5588] GAM387 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM387 was detected is described hereinabove with reference to Figs. 2-8.

[5589] GAM387 gene, herein designated GAM GENE, and GAM387 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5590] GAM387 gene, herein designated GAM GENE, encodes a GAM387 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM387 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM387 precursor RNA is designated SEQ ID:5985, and is provided hereinbelow with reference to the sequence listing part.

[5591] GAM387 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM387 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5592] An enzyme complex designated DICER COMPLEX, dices

the GAM387 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM387 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM387 RNA is designated SEQ ID:5986, and is provided hereinbelow with reference to the sequence listing part.

[5593] GAM387 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM387 target RNA, herein designated GAM TARGET RNA. GAM387 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5594] GAM387 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM387 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM387

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM387 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM387 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5595] The complementary binding of GAM387 RNA, herein designated GAM RNA, to target binding sites on GAM387 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM387 target RNA, herein designated GAM TARGET RNA, into GAM387 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5596] It is appreciated that GAM387 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM387 target genes. The mRNA of each one of this plurality of GAM387 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM387 RNA, herein designated GAM RNA, and which when bound by GAM387 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM387 target proteins.

[5597] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM387 gene, herein designated GAM GENE, on one or more GAM387 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5598] It is yet further appreciated that specific functions, and accordingly utilities, of GAM387 correlate with, and may be deduced from, the identity of the target genes which GAM387 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5599] Nucleotide sequences of the GAM387 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM387 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM387 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM387 are further described hereinbelow with reference to Table Table1.

[5600] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM387 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5601]

[5602] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 388 (GAM388) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5603] GAM388 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM388 was detected is described hereinabove with reference to Figs. 2-8.

[5604] GAM388 gene, herein designated GAM GENE, and GAM388 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5605] GAM388 gene, herein designated GAM GENE, encodes a GAM388 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM388 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM388 precursor RNA is designated SEQ ID:6007, and is provided hereinbelow with reference to the sequence listing part.

[5606] GAM388 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM388 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5607] An enzyme complex designated DICER COMPLEX, dices the GAM388 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM388 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM388 RNA is designated SEQ ID:6008, and is provided hereinbelow with reference to the sequence listing part.

[5608] GAM388 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM388 target RNA, herein designated GAM TARGET RNA. GAM388 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5609] GAM388 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM388 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM388 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM388 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM388 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[5610] The complementary binding of GAM388 RNA, herein designated GAM RNA, to target binding sites on GAM388 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM388 target RNA, herein designated GAM TARGET RNA, into GAM388 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5611] It is appreciated that GAM388 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM388 target genes. The mRNA of each one of this plurality of GAM388 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM388 RNA, herein designated GAM RNA, and which when bound by GAM388 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM388 target proteins.

[5612] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM388 gene, herein designated GAM GENE, on one or

more GAM388 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5613] It is yet further appreciated that specific functions, and accordingly utilities, of GAM388 correlate with, and may be deduced from, the identity of the target genes which GAM388 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5614] Nucleotide sequences of the GAM388 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM388 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM388 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM388 are further de-

scribed hereinbelow with reference to Table Table1.

[5615] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM388 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5616]

[5617] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 389 (GAM389) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5618] GAM389 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM389 was detected is described hereinabove with reference to Figs. 2-8.

[5619] GAM389 gene, herein designated GAM GENE, and GAM389 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5620] GAM389 gene, herein designated GAM GENE, encodes a GAM389 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM389 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM389 precursor RNA is designated SEQ ID:6019, and is provided hereinbelow with reference to the sequence listing part.

[5621] GAM389 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM389 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5622] An enzyme complex designated DICER COMPLEX, dices the GAM389 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM389 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM389 RNA is designated SEQ ID:6020, and is provided hereinbelow with reference to the sequence listing part.

[5623] GAM389 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM389 target RNA, herein designated GAM TARGET RNA. GAM389 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5624] GAM389 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM389 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM389 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM389 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM389 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5625] The complementary binding of GAM389 RNA, herein designated GAM RNA, to target binding sites on GAM389 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM389 target RNA, herein designated GAM TARGET RNA, into GAM389 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5626] It is appreciated that GAM389 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM389 target genes. The mRNA of each one of this plurality of GAM389 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM389 RNA, herein designated GAM RNA, and which when bound by GAM389 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM389 target proteins.

[5627] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM389 gene, herein designated GAM GENE, on one or more GAM389 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5628] It is yet further appreciated that specific functions, and accordingly utilities, of GAM389 correlate with, and may

be deduced from, the identity of the target genes which GAM389 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5629] Nucleotide sequences of the GAM389 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM389 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM389 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM389 are further described hereinbelow with reference to Table Table1.

[5630] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM389 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5631]

[5632] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 390 (GAM390) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5633] GAM390 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM390 was detected is described hereinabove with reference to Figs. 2-8.

[5634] GAM390 gene, herein designated GAM GENE, and GAM390 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5635] GAM390 gene, herein designated GAM GENE, encodes a GAM390 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM390 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM390 precursor RNA is designated SEQ ID:6033, and is provided hereinbelow with reference to the sequence listing part.

[5636] GAM390 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM390 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5637] An enzyme complex designated DICER COMPLEX, dices the GAM390 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM390 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM390 RNA is designated SEQ ID:6034, and is provided hereinbelow with reference to the sequence listing part.

[5638] GAM390 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM390 target RNA, herein designated GAM TARGET RNA. GAM390 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5639] GAM390 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM390 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM390 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM390 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM390 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5640] The complementary binding of GAM390 RNA, herein designated GAM RNA, to target binding sites on GAM390 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM390 target RNA, herein designated GAM TARGET RNA, into GAM390 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5641] It is appreciated that GAM390 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM390 target genes. The mRNA of each one of this plurality of GAM390 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM390 RNA, herein designated GAM RNA, and which when bound by GAM390 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM390 target proteins.

[5642] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM390 gene, herein designated GAM GENE, on one or more GAM390 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5643] It is yet further appreciated that specific functions, and accordingly utilities, of GAM390 correlate with, and may be deduced from, the identity of the target genes which GAM390 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5644] Nucleotide sequences of the GAM390 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM390 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM390 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM390 are further described hereinbelow with reference to Table Table1.

[5645] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM390 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5646]

[5647] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 391 (GAM391) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5648] GAM391 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM391 was detected is described hereinabove with reference to Figs. 2-8.

[5649] GAM391 gene, herein designated GAM GENE, and GAM391 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5650] GAM391 gene, herein designated GAM GENE, encodes a GAM391 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM391 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM391 precursor RNA is desig-

nated SEQ ID:6044, and is provided hereinbelow with reference to the sequence listing part.

[5651] GAM391 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM391 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5652] An enzyme complex designated DICER COMPLEX, dices the GAM391 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM391 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 42%) nucleotide sequence of GAM391 RNA is designated SEQ ID:6045, and is provided hereinbelow with reference to the sequence listing part.

[5653] GAM391 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM391 target RNA, herein designated GAM TARGET RNA. GAM391 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5654] GAM391 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM391 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM391 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM391 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM391

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5655] The complementary binding of GAM391 RNA, herein designated GAM RNA, to target binding sites on GAM391 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM391 target RNA, herein designated GAM TARGET RNA, into GAM391 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5656] It is appreciated that GAM391 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM391 target genes. The mRNA of each one of this plurality of GAM391 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM391 RNA, herein designated GAM RNA, and which when bound by GAM391 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM391 target proteins.

[5657] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM391 gene, herein designated GAM GENE, on one or more GAM391 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5658] It is yet further appreciated that specific functions, and accordingly utilities, of GAM391 correlate with, and may be deduced from, the identity of the target genes which GAM391 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5659] Nucleotide sequences of the GAM391 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM391 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM391 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM391 are further described hereinbelow with reference to Table Table1.

[5660] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM391 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5661]

[5662] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 392 (GAM392) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5663] GAM392 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM392 was detected is described hereinabove with reference to Figs. 2-8.

[5664] GAM392 gene, herein designated GAM GENE, and

GAM392 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5665] GAM392 gene, herein designated GAM GENE, encodes a GAM392 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM392 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM392 precursor RNA is designated SEQ ID:6066, and is provided hereinbelow with reference to the sequence listing part.

[5666] GAM392 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM392 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5667] An enzyme complex designated DICER COMPLEX, dices the GAM392 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM392 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 44%) nucleotide sequence of GAM392 RNA is designated SEQ ID:6067, and is provided hereinbelow with reference to the sequence listing part.

[5668] GAM392 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM392 target RNA, herein designated GAM TARGET RNA. GAM392 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5669] GAM392 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM392 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM392 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM392 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM392 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5670] The complementary binding of GAM392 RNA, herein designated GAM RNA, to target binding sites on GAM392 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM392 target RNA, herein designated GAM TARGET RNA, into GAM392 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5671] It is appreciated that GAM392 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM392 target genes. The mRNA of each one of this plurality of GAM392 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM392 RNA, herein designated GAM RNA, and which when bound by GAM392 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM392 target proteins.

[5672] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM392 gene, herein designated GAM GENE, on one or more GAM392 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5673] It is yet further appreciated that specific functions, and accordingly utilities, of GAM392 correlate with, and may be deduced from, the identity of the target genes which GAM392 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5674] Nucleotide sequences of the GAM392 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM392 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM392 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM392 are further described hereinbelow with reference to Table Table1.

[5675] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM392 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5676]

[5677] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 393 (GAM393) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5678] GAM393 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM393 was detected is described hereinabove with reference to Figs. 2-8.

[5679] GAM393 gene, herein designated GAM GENE, and GAM393 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5680] GAM393 gene, herein designated GAM GENE, encodes a GAM393 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM393 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM393 precursor RNA is designated SEQ ID:6072, and is provided hereinbelow with reference to the sequence listing part.

[5681] GAM393 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM393 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5682] An enzyme complex designated DICER COMPLEX, dices the GAM393 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM393 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM393 RNA is designated SEQ ID:6073, and is provided hereinbelow with reference to the sequence listing part.

[5683] GAM393 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM393 target RNA, herein designated GAM TARGET RNA. GAM393 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5684] GAM393 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM393 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM393 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM393 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM393 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5685] The complementary binding of GAM393 RNA, herein designated GAM RNA, to target binding sites on GAM393 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM393 target RNA, herein designated GAM TARGET RNA, into GAM393 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5686] It is appreciated that GAM393 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM393 target genes. The mRNA of each one of this plurality of GAM393 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM393 RNA, herein designated GAM RNA, and which when bound by GAM393 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM393 target proteins.

[5687] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM393 gene, herein designated GAM GENE, on one or more GAM393 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5688] It is yet further appreciated that specific functions, and accordingly utilities, of GAM393 correlate with, and may be deduced from, the identity of the target genes which GAM393 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5689] Nucleotide sequences of the GAM393 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM393 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM393 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM393 are further described hereinbelow with reference to Table Table1.

[5690] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM393 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5691]

[5692] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 394 (GAM394) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5693] GAM394 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM394 was detected is described hereinabove with reference to Figs. 2-8.

[5694] GAM394 gene, herein designated GAM GENE, and GAM394 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5695] GAM394 gene, herein designated GAM GENE, encodes a GAM394 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM394 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM394 precursor RNA is designated SEQ ID:6089, and is provided hereinbelow with reference to the sequence listing part.

[5696] GAM394 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM394 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5697] An enzyme complex designated DICER COMPLEX, dices the GAM394 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM394 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM394 RNA is designated SEQ ID:6090, and is provided hereinbelow with reference to the sequence listing part.

[5698] GAM394 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM394 target RNA, herein designated GAM TARGET RNA. GAM394 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5699] GAM394 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM394 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM394 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM394 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM394 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5700] The complementary binding of GAM394 RNA, herein designated GAM RNA, to target binding sites on GAM394 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM394 target RNA, herein designated GAM TARGET RNA, into GAM394 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5701] It is appreciated that GAM394 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM394 target genes. The mRNA of each one of this plurality of GAM394 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM394 RNA,

herein designated GAM RNA, and which when bound by GAM394 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM394 target proteins.

[5702] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM394 gene, herein designated GAM GENE, on one or more GAM394 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5703] It is yet further appreciated that specific functions, and accordingly utilities, of GAM394 correlate with, and may be deduced from, the identity of the target genes which

GAM394 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5704] Nucleotide sequences of the GAM394 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM394 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM394 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM394 are further described hereinbelow with reference to Table Table1.

[5705] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM394 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5706]

[5707] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 395 (GAM395) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5708] GAM395 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM395 was detected is described hereinabove with reference to Figs. 2-8.

[5709] GAM395 gene, herein designated GAM GENE, and GAM395 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5710] GAM395 gene, herein designated GAM GENE, encodes a GAM395 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM395 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM395 precursor RNA is designated SEQ ID:6103, and is provided hereinbelow with reference to the sequence listing part.

[5711] GAM395 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM395 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[5712] An enzyme complex designated DICER COMPLEX, dices the GAM395 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM395 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 24%) nucleotide sequence of GAM395 RNA is designated SEQ ID:6104, and is provided hereinbelow with reference to the sequence listing part.

[5713] GAM395 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM395 target RNA, herein designated GAM TARGET RNA.
GAM395 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5714] GAM395 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM395 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM395 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM395 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM395 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5715] The complementary binding of GAM395 RNA, herein designated GAM RNA, to target binding sites on GAM395 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM395 target RNA, herein desig-

nated GAM TARGET RNA, into GAM395 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5716] It is appreciated that GAM395 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM395 target genes. The mRNA of each one of this plurality of GAM395 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM395 RNA, herein designated GAM RNA, and which when bound by GAM395 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM395 target proteins.

[5717] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM395 gene, herein designated GAM GENE, on one or more GAM395 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5718] It is yet further appreciated that specific functions, and accordingly utilities, of GAM395 correlate with, and may be deduced from, the identity of the target genes which GAM395 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5719] Nucleotide sequences of the GAM395 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM395 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM395 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM395 are further described hereinbelow with reference to Table Table1.

[5720] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM395 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[5721]

[5722] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 396 (GAM396) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5723] GAM396 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM396 was detected is described hereinabove with reference to Figs. 2-8.

[5724] GAM396 gene, herein designated GAM GENE, and GAM396 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5725] GAM396 gene, herein designated GAM GENE, encodes a GAM396 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM396 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM396 precursor RNA is designated SEQ ID:6117, and is provided hereinbelow with ref-

erence to the sequence listing part.

[5726] GAM396 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM396 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5727] An enzyme complex designated DICER COMPLEX, dices the GAM396 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM396 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM396 RNA is designated SEQ ID:6118, and is provided hereinbelow with reference to the sequence listing part.

[5728] GAM396 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM396 target RNA, herein designated GAM TARGET RNA.

GAM396 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5729] GAM396 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM396 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM396 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM396 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM396 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5730] The complementary binding of GAM396 RNA, herein designated GAM RNA, to target binding sites on GAM396 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM396 target RNA, herein designated GAM TARGET RNA, into GAM396 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5731] It is appreciated that GAM396 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM396 target genes. The mRNA of each one of this plurality of GAM396 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM396 RNA, herein designated GAM RNA, and which when bound by GAM396 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM396 target proteins.

[5732] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM396 gene, herein designated GAM GENE, on one or more GAM396 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5733] It is yet further appreciated that specific functions, and accordingly utilities, of GAM396 correlate with, and may be deduced from, the identity of the target genes which GAM396 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5734] Nucleotide sequences of the GAM396 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM396 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM396 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM396 are further described hereinbelow with reference to Table Table1.

[5735] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM396 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5736]

[5737] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 397 (GAM397) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5738] GAM397 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM397 was detected is described hereinabove with reference to Figs. 2-8.

[5739] GAM397 gene, herein designated GAM GENE, and GAM397 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[5740] GAM397 gene, herein designated GAM GENE, encodes a GAM397 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM397 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM397 precursor RNA is designated SEQ ID:6135, and is provided hereinbelow with reference to the sequence listing part.

[5741] GAM397 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM397 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5742] An enzyme complex designated DICER COMPLEX, dices the GAM397 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM397 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 44%) nucleotide sequence of GAM397 RNA is designated SEQ ID:6136, and is provided hereinbelow with reference to the sequence listing part.

[5743] GAM397 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM397 target RNA, herein designated GAM TARGET RNA. GAM397 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5744] GAM397 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM397 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM397 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM397 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM397 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5745] The complementary binding of GAM397 RNA, herein designated GAM RNA, to target binding sites on GAM397 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM397 target RNA, herein designated GAM TARGET RNA, into GAM397 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5746] It is appreciated that GAM397 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM397 target genes. The mRNA of each one of this plurality of GAM397 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM397 RNA, herein designated GAM RNA, and which when bound by GAM397 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM397 target proteins.

[5747] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM397 gene, herein designated GAM GENE, on one or more GAM397 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[5748] It is yet further appreciated that specific functions, and accordingly utilities, of GAM397 correlate with, and may be deduced from, the identity of the target genes which GAM397 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5749] Nucleotide sequences of the GAM397 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM397 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM397 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM397 are further described hereinbelow with reference to Table Table1.

[5750] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM397 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5751]

[5752] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

398 (GAM398) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5753] GAM398 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM398 was detected is described hereinabove with reference to Figs. 2-8.

[5754] GAM398 gene, herein designated GAM GENE, and GAM398 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5755] GAM398 gene, herein designated GAM GENE, encodes a GAM398 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM398 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM398 precursor RNA is designated SEQ ID:6161, and is provided hereinbelow with reference to the sequence listing part.

[5756] GAM398 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM398 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5757] An enzyme complex designated DICER COMPLEX, dices the GAM398 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM398 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM398 RNA is designated SEQ ID:6162, and is provided hereinbelow with reference to the sequence listing part.

[5758] GAM398 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM398 target RNA, herein designated GAM TARGET RNA. GAM398 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5759] GAM398 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM398 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM398 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM398 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM398 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5760] The complementary binding of GAM398 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM398 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM398 target RNA, herein designated GAM TARGET RNA, into GAM398 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5761] It is appreciated that GAM398 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM398 target genes. The mRNA of each one of this plurality of GAM398 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM398 RNA, herein designated GAM RNA, and which when bound by GAM398 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM398 target proteins.

[5762] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM398 gene, herein designated GAM GENE, on one or more GAM398 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5763] It is yet further appreciated that specific functions, and accordingly utilities, of GAM398 correlate with, and may be deduced from, the identity of the target genes which GAM398 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5764] Nucleotide sequences of the GAM398 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM398 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM398 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM398 are further described hereinbelow with reference to Table Table1.

[5765] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM398 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5766]

[5767] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 399 (GAM399) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5768] GAM399 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM399 was detected is described hereinabove with reference to Figs. 2-8.

[5769] GAM399 gene, herein designated GAM GENE, and GAM399 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5770] GAM399 gene, herein designated GAM GENE, encodes a GAM399 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM399 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM399 precursor RNA is designated SEQ ID:6189, and is provided hereinbelow with reference to the sequence listing part.

[5771] GAM399 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM399 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5772] An enzyme complex designated DICER COMPLEX, dices the GAM399 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM399 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 58%) nucleotide sequence of GAM399 RNA is designated SEQ ID:6190, and is provided hereinbelow with reference to the sequence listing part.

[5773] GAM399 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM399 target RNA, herein designated GAM TARGET RNA. GAM399 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5774] GAM399 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM399 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM399 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM399 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM399 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5775] The complementary binding of GAM399 RNA, herein designated GAM RNA, to target binding sites on GAM399 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM399 target RNA, herein designated GAM TARGET RNA, into GAM399 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5776] It is appreciated that GAM399 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM399 target genes. The mRNA of each one of this plurality of GAM399 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM399 RNA, herein designated GAM RNA, and which when bound by

GAM399 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM399 target proteins.

[5777] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM399 gene, herein designated GAM GENE, on one or more GAM399 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5778] It is yet further appreciated that specific functions, and accordingly utilities, of GAM399 correlate with, and may be deduced from, the identity of the target genes which GAM399 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[5779] Nucleotide sequences of the GAM399 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM399 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM399 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM399 are further described hereinbelow with reference to Table Table1.

[5780] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM399 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5781]

[5782] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 400 (GAM400) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5783] GAM400 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM400 was detected is described hereinabove with reference to Figs. 2-8.

[5784] GAM400 gene, herein designated GAM GENE, and GAM400 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5785] GAM400 gene, herein designated GAM GENE, encodes a GAM400 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM400 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM400 precursor RNA is designated SEQ ID:6197, and is provided hereinbelow with reference to the sequence listing part.

[5786] GAM400 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM400 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[5787] An enzyme complex designated DICER COMPLEX, dices the GAM400 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM400 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM400 RNA is designated SEQ ID:6198, and is provided hereinbelow with reference to the sequence listing part.

[5788] GAM400 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM400 target RNA, herein designated GAM TARGET RNA. GAM400 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5789] GAM400 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM400 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM400 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM400 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM400 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5790] The complementary binding of GAM400 RNA, herein designated GAM RNA, to target binding sites on GAM400 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM400 target RNA, herein designated GAM TARGET RNA, into GAM400 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5791] It is appreciated that GAM400 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM400 target genes. The mRNA of each one of this plurality of GAM400 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM400 RNA, herein designated GAM RNA, and which when bound by GAM400 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM400 target proteins.

[5792] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM400 gene, herein designated GAM GENE, on one or more GAM400 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5793] It is yet further appreciated that specific functions, and accordingly utilities, of GAM400 correlate with, and may be deduced from, the identity of the target genes which GAM400 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5794] Nucleotide sequences of the GAM400 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM400 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM400 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM400 are further described hereinbelow with reference to Table Table1.

[5795] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM400 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5796]

[5797] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 401 (GAM401) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5798] GAM401 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM401 was detected is described hereinabove with reference to Figs. 2-8.

[5799] GAM401 gene, herein designated GAM GENE, and GAM401 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5800] GAM401 gene, herein designated GAM GENE, encodes a GAM401 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM401 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM401 precursor RNA is designated SEQ ID:6201, and is provided hereinbelow with reference to the sequence listing part.

[5801] GAM401 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM401 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5802] An enzyme complex designated DICER COMPLEX, dices the GAM401 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM401 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM401 RNA is designated SEQ ID:6202, and is provided hereinbelow with reference to the sequence listing part.

[5803] GAM401 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM401

target RNA, herein designated GAM TARGET RNA.

GAM401 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5804] GAM401 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM401 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM401 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM401 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM401 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5805] The complementary binding of GAM401 RNA, herein designated GAM RNA, to target binding sites on GAM401 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM401 target RNA, herein designated GAM TARGET RNA, into GAM401 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5806] It is appreciated that GAM401 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM401 target genes. The mRNA of each one of this plurality of GAM401 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM401 RNA, herein designated GAM RNA, and which when bound by GAM401 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM401 target proteins.

[5807] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM401 gene, herein designated GAM GENE, on one or more GAM401 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5808] It is yet further appreciated that specific functions, and accordingly utilities, of GAM401 correlate with, and may be deduced from, the identity of the target genes which GAM401 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5809] Nucleotide sequences of the GAM401 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM401 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM401 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM401 are further described hereinbelow with reference to Table Table1.

[5810] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM401 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5811]

[5812] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 402 (GAM402) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5813] GAM402 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM402 was detected is described hereinabove with reference to Figs. 2-8.

[5814] GAM402 gene, herein designated GAM GENE, and GAM402 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5815] GAM402 gene, herein designated GAM GENE, encodes a GAM402 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM402 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM402 precursor RNA is designated SEQ ID:6210, and is provided hereinbelow with reference to the sequence listing part.

[5816] GAM402 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM402 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5817] An enzyme complex designated DICER COMPLEX, dices the GAM402 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM402 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM402 RNA is designated SEQ ID:6211, and is provided hereinbelow with reference to the sequence listing part.

[5818] GAM402 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM402 target RNA, herein designated GAM TARGET RNA. GAM402 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5819] GAM402 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM402 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM402 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM402 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM402 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5820] The complementary binding of GAM402 RNA, herein designated GAM RNA, to target binding sites on GAM402 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM402 target RNA, herein designated GAM TARGET RNA, into GAM402 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5821] It is appreciated that GAM402 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM402 target genes. The mRNA of each one of this plu-

rality of GAM402 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM402 RNA, herein designated GAM RNA, and which when bound by GAM402 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM402 target proteins.

[5822] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM402 gene, herein designated GAM GENE, on one or more GAM402 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5823] It is yet further appreciated that specific functions, and accordingly utilities, of GAM402 correlate with, and may be deduced from, the identity of the target genes which GAM402 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5824] Nucleotide sequences of the GAM402 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM402 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM402 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM402 are further described hereinbelow with reference to Table Table1.

[5825] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM402 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5826]

[5827] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 403 (GAM403) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[5828] GAM403 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM403 was detected is described hereinabove with reference to Figs. 2-8.

[5829] GAM403 gene, herein designated GAM GENE, and GAM403 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5830] GAM403 gene, herein designated GAM GENE, encodes a GAM403 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM403 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM403 precursor RNA is designated SEQ ID:6262, and is provided hereinbelow with reference to the sequence listing part.

[5831] GAM403 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM403 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5832] An enzyme complex designated DICER COMPLEX, dices the GAM403 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM403 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 39%) nucleotide sequence of GAM403 RNA is designated SEQ ID:6263, and is provided hereinbelow with reference to the sequence listing part.

[5833] GAM403 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM403 target RNA, herein designated GAM TARGET RNA.
GAM403 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[5834] GAM403 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM403 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM403 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM403 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM403 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5835] The complementary binding of GAM403 RNA, herein designated GAM RNA, to target binding sites on GAM403 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM403 target RNA, herein designated GAM TARGET RNA, into GAM403 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5836] It is appreciated that GAM403 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM403 target genes. The mRNA of each one of this plurality of GAM403 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM403 RNA, herein designated GAM RNA, and which when bound by GAM403 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM403 target proteins.

[5837] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM403 gene, herein designated GAM GENE, on one or more GAM403 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5838] It is yet further appreciated that specific functions, and accordingly utilities, of GAM403 correlate with, and may be deduced from, the identity of the target genes which GAM403 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5839] Nucleotide sequences of the GAM403 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM403 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM403 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM403 are further described hereinbelow with reference to Table Table1.

[5840] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM403 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5841]

[5842] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 404 (GAM404) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5843] GAM404 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM404 was detected is described hereinabove with reference to Figs. 2-8.

[5844] GAM404 gene, herein designated GAM GENE, and GAM404 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5845] GAM404 gene, herein designated GAM GENE, encodes a GAM404 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM404 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM404 precursor RNA is designated SEQ ID:6289, and is provided hereinbelow with reference to the sequence listing part.

[5846] GAM404 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM404 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5847] An enzyme complex designated DICER COMPLEX, dices the GAM404 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM404 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of

GAM404 RNA is designated SEQ ID:6290, and is provided hereinbelow with reference to the sequence listing part.

[5848] GAM404 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM404 target RNA, herein designated GAM TARGET RNA. GAM404 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5849] GAM404 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM404 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM404 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM404 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM404 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5850] The complementary binding of GAM404 RNA, herein designated GAM RNA, to target binding sites on GAM404 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM404 target RNA, herein designated GAM TARGET RNA, into GAM404 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5851] It is appreciated that GAM404 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM404 target genes. The mRNA of each one of this plurality of GAM404 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM404 RNA, herein designated GAM RNA, and which when bound by GAM404 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM404 target proteins.

[5852] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM404 gene, herein designated GAM GENE, on one or more GAM404 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5853] It is yet further appreciated that specific functions, and accordingly utilities, of GAM404 correlate with, and may be deduced from, the identity of the target genes which GAM404 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5854] Nucleotide sequences of the GAM404 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM404 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM404 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM404 are further described hereinbelow with reference to Table Table1.

[5855] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM404 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5856]

[5857] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 405 (GAM405) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5858] GAM405 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM405 was detected is described hereinabove

with reference to Figs. 2-8.

[5859] GAM405 gene, herein designated GAM GENE, and GAM405 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5860] GAM405 gene, herein designated GAM GENE, encodes a GAM405 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM405 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM405 precursor RNA is designated SEQ ID:6304, and is provided hereinbelow with reference to the sequence listing part.

[5861] GAM405 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM405 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5862] An enzyme complex designated DICER COMPLEX, dices the GAM405 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM405 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 22%) nucleotide sequence of GAM405 RNA is designated SEQ ID:6305, and is provided hereinbelow with reference to the sequence listing part.

[5863] GAM405 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM405 target RNA, herein designated GAM TARGET RNA. GAM405 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5864] GAM405 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM405 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM405 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM405 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM405 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5865] The complementary binding of GAM405 RNA, herein designated GAM RNA, to target binding sites on GAM405 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM405 target RNA, herein designated GAM TARGET RNA, into GAM405 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[5866] It is appreciated that GAM405 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM405 target genes. The mRNA of each one of this plurality of GAM405 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM405 RNA, herein designated GAM RNA, and which when bound by GAM405 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM405 target proteins.

[5867] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM405 gene, herein designated GAM GENE, on one or more GAM405 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5868] It is yet further appreciated that specific functions, and accordingly utilities, of GAM405 correlate with, and may be deduced from, the identity of the target genes which GAM405 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5869] Nucleotide sequences of the GAM405 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM405 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM405 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM405 are further described hereinbelow with reference to Table Table1.

[5870] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM405 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5871]

[5872] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 406 (GAM406) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5873] GAM406 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM406 was detected is described hereinabove with reference to Figs. 2-8.

[5874] GAM406 gene, herein designated GAM GENE, and GAM406 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5875] GAM406 gene, herein designated GAM GENE, encodes a GAM406 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM406 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM406 precursor RNA is designated SEQ ID:6311, and is provided hereinbelow with reference to the sequence listing part.

[5876] GAM406 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM406 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5877] An enzyme complex designated DICER COMPLEX, dices the GAM406 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM406 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM406 RNA is designated SEQ ID:6312, and is provided hereinbelow with reference to the sequence listing part.

[5878] GAM406 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM406 target RNA, herein designated GAM TARGET RNA.

GAM406 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5879] GAM406 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM406 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM406 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM406 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM406 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5880] The complementary binding of GAM406 RNA, herein designated GAM RNA, to target binding sites on GAM406 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM406 target RNA, herein designated GAM TARGET RNA, into GAM406 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5881] It is appreciated that GAM406 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM406 target genes. The mRNA of each one of this plurality of GAM406 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM406 RNA, herein designated GAM RNA, and which when bound by GAM406 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM406 target proteins.

[5882] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM406 gene, herein designated GAM GENE, on one or more GAM406 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5883] It is yet further appreciated that specific functions, and accordingly utilities, of GAM406 correlate with, and may be deduced from, the identity of the target genes which GAM406 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5884] Nucleotide sequences of the GAM406 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM406 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM406 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM406 are further described hereinbelow with reference to Table Table1.

[5885] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM406 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5886]

[5887] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 407 (GAM407) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5888] GAM407 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM407 was detected is described hereinabove with reference to Figs. 2-8.

[5889] GAM407 gene, herein designated GAM GENE, and GAM407 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5890] GAM407 gene, herein designated GAM GENE, encodes a

GAM407 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM407 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM407 precursor RNA is designated SEQ ID:6329, and is provided hereinbelow with reference to the sequence listing part.

[5891] GAM407 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM407 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5892] An enzyme complex designated DICER COMPLEX, dices the GAM407 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM407 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM407 RNA is designated SEQ ID:6330, and is provided hereinbelow with reference to the sequence listing part.

[5893] GAM407 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM407 target RNA, herein designated GAM TARGET RNA. GAM407 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5894] GAM407 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM407 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM407 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM407 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM407 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5895] The complementary binding of GAM407 RNA, herein designated GAM RNA, to target binding sites on GAM407 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM407 target RNA, herein designated GAM TARGET RNA, into GAM407 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5896] It is appreciated that GAM407 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM407 target genes. The mRNA of each one of this plurality of GAM407 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM407 RNA, herein designated GAM RNA, and which when bound by GAM407 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM407 target proteins.

[5897] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM407 gene, herein designated GAM GENE, on one or more GAM407 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5898] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM407 correlate with, and may be deduced from, the identity of the target genes which GAM407 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5899] Nucleotide sequences of the GAM407 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM407 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM407 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM407 are further described hereinbelow with reference to Table Table1.

[5900] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM407 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5901]

[5902] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 408 (GAM408) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[5903] GAM408 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM408 was detected is described hereinabove with reference to Figs. 2-8.

[5904] GAM408 gene, herein designated GAM GENE, and GAM408 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5905] GAM408 gene, herein designated GAM GENE, encodes a GAM408 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM408 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM408 precursor RNA is designated SEQ ID:6357, and is provided hereinbelow with reference to the sequence listing part.

[5906] GAM408 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM408 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5907] An enzyme complex designated DICER COMPLEX, dices the GAM408 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM408 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM408 RNA is designated SEQ ID:6358, and is provided hereinbelow with reference to the sequence listing part.

[5908] GAM408 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM408 target RNA, herein designated GAM TARGET RNA. GAM408 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5909] GAM408 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM408 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM408 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM408 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM408 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5910] The complementary binding of GAM408 RNA, herein designated GAM RNA, to target binding sites on GAM408 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM408 target RNA, herein designated GAM TARGET RNA, into GAM408 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5911] It is appreciated that GAM408 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM408 target genes. The mRNA of each one of this plurality of GAM408 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM408 RNA, herein designated GAM RNA, and which when bound by GAM408 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM408 target proteins.

[5912] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM408 gene, herein designated GAM GENE, on one or more GAM408 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5913] It is yet further appreciated that specific functions, and accordingly utilities, of GAM408 correlate with, and may be deduced from, the identity of the target genes which GAM408 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5914] Nucleotide sequences of the GAM408 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM408 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM408 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM408 are further described hereinbelow with reference to Table Table1.

[5915] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM408 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5916]

[5917] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 409 (GAM409) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5918] GAM409 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM409 was detected is described hereinabove with reference to Figs. 2-8.

[5919] GAM409 gene, herein designated GAM GENE, and GAM409 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5920] GAM409 gene, herein designated GAM GENE, encodes a GAM409 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM409 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM409 precursor RNA is designated SEQ ID:6372, and is provided hereinbelow with reference to the sequence listing part.

[5921] GAM409 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM409 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5922] An enzyme complex designated DICER COMPLEX, dices the GAM409 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM409 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM409 RNA is designated SEQ ID:6373, and is provided

hereinbelow with reference to the sequence listing part.

[5923] GAM409 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM409 target RNA, herein designated GAM TARGET RNA.
GAM409 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5924] GAM409 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM409 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM409 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM409 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM409 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5925] The complementary binding of GAM409 RNA, herein designated GAM RNA, to target binding sites on GAM409 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM409 target RNA, herein designated GAM TARGET RNA, into GAM409 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5926] It is appreciated that GAM409 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM409 target genes. The mRNA of each one of this plurality of GAM409 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM409 RNA, herein designated GAM RNA, and which when bound by GAM409 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM409 tar-

get proteins.

[5927] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM409 gene, herein designated GAM GENE, on one or more GAM409 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5928] It is yet further appreciated that specific functions, and accordingly utilities, of GAM409 correlate with, and may be deduced from, the identity of the target genes which GAM409 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5929] Nucleotide sequences of the GAM409 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM409 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM409 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM409 are further described hereinbelow with reference to Table Table1.

[5930] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM409 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5931]

[5932] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 410 (GAM410) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5933] GAM410 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM410 was detected is described hereinabove with reference to Figs. 2-8.

[5934] GAM410 gene, herein designated GAM GENE, and GAM410 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5935] GAM410 gene, herein designated GAM GENE, encodes a GAM410 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM410 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM410 precursor RNA is designated SEQ ID:6380, and is provided hereinbelow with reference to the sequence listing part.

[5936] GAM410 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM410 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5937] An enzyme complex designated DICER COMPLEX, dices

the GAM410 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM410 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM410 RNA is designated SEQ ID:6381, and is provided hereinbelow with reference to the sequence listing part.

[5938] GAM410 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM410 target RNA, herein designated GAM TARGET RNA. GAM410 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5939] GAM410 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM410 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM410

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM410 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM410 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5940] The complementary binding of GAM410 RNA, herein designated GAM RNA, to target binding sites on GAM410 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM410 target RNA, herein designated GAM TARGET RNA, into GAM410 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5941] It is appreciated that GAM410 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM410 target genes. The mRNA of each one of this plurality of GAM410 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM410 RNA, herein designated GAM RNA, and which when bound by GAM410 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM410 target proteins.

[5942] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM410 gene, herein designated GAM GENE, on one or more GAM410 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5943] It is yet further appreciated that specific functions, and accordingly utilities, of GAM410 correlate with, and may be deduced from, the identity of the target genes which GAM410 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5944] Nucleotide sequences of the GAM410 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM410 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM410 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM410 are further described hereinbelow with reference to Table Table1.

[5945] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM410 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5946]

[5947] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 411 (GAM411) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5948] GAM411 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM411 was detected is described hereinabove with reference to Figs. 2-8.

[5949] GAM411 gene, herein designated GAM GENE, and GAM411 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5950] GAM411 gene, herein designated GAM GENE, encodes a GAM411 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM411 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM411 precursor RNA is designated SEQ ID:6419, and is provided hereinbelow with reference to the sequence listing part.

[5951] GAM411 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM411 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5952] An enzyme complex designated DICER COMPLEX, dices the GAM411 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM411 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM411 RNA is designated SEQ ID:6420, and is provided hereinbelow with reference to the sequence listing part.

[5953] GAM411 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM411 target RNA, herein designated GAM TARGET RNA. GAM411 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5954] GAM411 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM411 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM411 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM411 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM411 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[5955] The complementary binding of GAM411 RNA, herein designated GAM RNA, to target binding sites on GAM411 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM411 target RNA, herein designated GAM TARGET RNA, into GAM411 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5956] It is appreciated that GAM411 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM411 target genes. The mRNA of each one of this plurality of GAM411 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM411 RNA, herein designated GAM RNA, and which when bound by GAM411 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM411 target proteins.

[5957] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM411 gene, herein designated GAM GENE, on one or

more GAM411 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5958] It is yet further appreciated that specific functions, and accordingly utilities, of GAM411 correlate with, and may be deduced from, the identity of the target genes which GAM411 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5959] Nucleotide sequences of the GAM411 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM411 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM411 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM411 are further de-

scribed hereinbelow with reference to Table Table1.

[5960] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM411 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5961]

[5962] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 412 (GAM412) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5963] GAM412 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM412 was detected is described hereinabove with reference to Figs. 2-8.

[5964] GAM412 gene, herein designated GAM GENE, and GAM412 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5965] GAM412 gene, herein designated GAM GENE, encodes a GAM412 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM412 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM412 precursor RNA is designated SEQ ID:6436, and is provided hereinbelow with reference to the sequence listing part.

[5966] GAM412 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM412 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5967] An enzyme complex designated DICER COMPLEX, dices the GAM412 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM412 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM412 RNA is designated SEQ ID:6437, and is provided hereinbelow with reference to the sequence listing part.

[5968] GAM412 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM412 target RNA, herein designated GAM TARGET RNA. GAM412 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5969] GAM412 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM412 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM412 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM412 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM412 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5970] The complementary binding of GAM412 RNA, herein designated GAM RNA, to target binding sites on GAM412 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM412 target RNA, herein designated GAM TARGET RNA, into GAM412 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5971] It is appreciated that GAM412 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM412 target genes. The mRNA of each one of this plurality of GAM412 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM412 RNA, herein designated GAM RNA, and which when bound by GAM412 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM412 target proteins.

[5972] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM412 gene, herein designated GAM GENE, on one or more GAM412 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5973] It is yet further appreciated that specific functions, and accordingly utilities, of GAM412 correlate with, and may

be deduced from, the identity of the target genes which GAM412 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5974] Nucleotide sequences of the GAM412 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM412 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM412 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM412 are further described hereinbelow with reference to Table Table1.

[5975] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM412 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5976]

[5977] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 413 (GAM413) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5978] GAM413 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM413 was detected is described hereinabove with reference to Figs. 2-8.

[5979] GAM413 gene, herein designated GAM GENE, and GAM413 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5980] GAM413 gene, herein designated GAM GENE, encodes a GAM413 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM413 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM413 precursor RNA is designated SEQ ID:6452, and is provided hereinbelow with reference to the sequence listing part.

[5981] GAM413 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM413 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5982] An enzyme complex designated DICER COMPLEX, dices the GAM413 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM413 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 41%) nucleotide sequence of GAM413 RNA is designated SEQ ID:6453, and is provided hereinbelow with reference to the sequence listing part.

[5983] GAM413 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM413 target RNA, herein designated GAM TARGET RNA. GAM413 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5984] GAM413 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM413 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM413 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM413 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM413 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[5985] The complementary binding of GAM413 RNA, herein designated GAM RNA, to target binding sites on GAM413 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM413 target RNA, herein designated GAM TARGET RNA, into GAM413 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[5986] It is appreciated that GAM413 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM413 target genes. The mRNA of each one of this plurality of GAM413 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM413 RNA, herein designated GAM RNA, and which when bound by GAM413 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM413 target proteins.

[5987] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM413 gene, herein designated GAM GENE, on one or more GAM413 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[5988] It is yet further appreciated that specific functions, and accordingly utilities, of GAM413 correlate with, and may be deduced from, the identity of the target genes which GAM413 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[5989] Nucleotide sequences of the GAM413 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM413 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM413 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM413 are further described hereinbelow with reference to Table Table1.

[5990] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM413 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[5991]

[5992] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 414 (GAM414) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[5993] GAM414 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM414 was detected is described hereinabove with reference to Figs. 2-8.

[5994] GAM414 gene, herein designated GAM GENE, and GAM414 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[5995] GAM414 gene, herein designated GAM GENE, encodes a GAM414 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM414 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM414 precursor RNA is desig-

nated SEQ ID:6474, and is provided hereinbelow with reference to the sequence listing part.

[5996] GAM414 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM414 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[5997] An enzyme complex designated DICER COMPLEX, dices the GAM414 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM414 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM414 RNA is designated SEQ ID:6475, and is provided hereinbelow with reference to the sequence listing part.

[5998] GAM414 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM414 target RNA, herein designated GAM TARGET RNA. GAM414 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[5999] GAM414 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM414 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM414 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM414 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM414

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6000] The complementary binding of GAM414 RNA, herein designated GAM RNA, to target binding sites on GAM414 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM414 target RNA, herein designated GAM TARGET RNA, into GAM414 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6001] It is appreciated that GAM414 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM414 target genes. The mRNA of each one of this plurality of GAM414 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM414 RNA, herein designated GAM RNA, and which when bound by GAM414 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM414 target proteins.

[6002] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM414 gene, herein designated GAM GENE, on one or more GAM414 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6003] It is yet further appreciated that specific functions, and accordingly utilities, of GAM414 correlate with, and may be deduced from, the identity of the target genes which GAM414 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6004] Nucleotide sequences of the GAM414 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM414 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM414 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM414 are further described hereinbelow with reference to Table Table1.

[6005] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM414 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6006]

[6007] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 415 (GAM415) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6008] GAM415 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM415 was detected is described hereinabove with reference to Figs. 2-8.

[6009] GAM415 gene, herein designated GAM GENE, and

GAM415 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6010] GAM415 gene, herein designated GAM GENE, encodes a GAM415 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM415 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM415 precursor RNA is designated SEQ ID:6489, and is provided hereinbelow with reference to the sequence listing part.

[6011] GAM415 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM415 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6012] An enzyme complex designated DICER COMPLEX, dices the GAM415 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM415 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM415 RNA is designated SEQ ID:6490, and is provided hereinbelow with reference to the sequence listing part.

[6013] GAM415 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM415 target RNA, herein designated GAM TARGET RNA. GAM415 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6014] GAM415 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM415 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM415 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM415 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM415 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6015] The complementary binding of GAM415 RNA, herein designated GAM RNA, to target binding sites on GAM415 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM415 target RNA, herein designated GAM TARGET RNA, into GAM415 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6016] It is appreciated that GAM415 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM415 target genes. The mRNA of each one of this plurality of GAM415 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM415 RNA, herein designated GAM RNA, and which when bound by GAM415 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM415 target proteins.

[6017] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM415 gene, herein designated GAM GENE, on one or more GAM415 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6018] It is yet further appreciated that specific functions, and accordingly utilities, of GAM415 correlate with, and may be deduced from, the identity of the target genes which GAM415 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6019] Nucleotide sequences of the GAM415 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM415 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM415 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM415 are further described hereinbelow with reference to Table Table1.

[6020] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM415 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6021]

[6022] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 416 (GAM416) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6023] GAM416 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM416 was detected is described hereinabove with reference to Figs. 2-8.

[6024] GAM416 gene, herein designated GAM GENE, and GAM416 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6025] GAM416 gene, herein designated GAM GENE, encodes a GAM416 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM416 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM416 precursor RNA is designated SEQ ID:6500, and is provided hereinbelow with reference to the sequence listing part.

[6026] GAM416 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM416 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6027] An enzyme complex designated DICER COMPLEX, dices the GAM416 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM416 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM416 RNA is designated SEQ ID:6501, and is provided hereinbelow with reference to the sequence listing part.

[6028] GAM416 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM416 target RNA, herein designated GAM TARGET RNA. GAM416 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6029] GAM416 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM416 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM416 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM416 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM416 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6030] The complementary binding of GAM416 RNA, herein designated GAM RNA, to target binding sites on GAM416 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM416 target RNA, herein designated GAM TARGET RNA, into GAM416 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6031] It is appreciated that GAM416 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM416 target genes. The mRNA of each one of this plurality of GAM416 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM416 RNA, herein designated GAM RNA, and which when bound by GAM416 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM416 target proteins.

[6032] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM416 gene, herein designated GAM GENE, on one or more GAM416 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6033] It is yet further appreciated that specific functions, and accordingly utilities, of GAM416 correlate with, and may be deduced from, the identity of the target genes which GAM416 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6034] Nucleotide sequences of the GAM416 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM416 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM416 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM416 are further described hereinbelow with reference to Table Table1.

[6035] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM416 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6036]

[6037] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 417 (GAM417) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6038] GAM417 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM417 was detected is described hereinabove with reference to Figs. 2-8.

[6039] GAM417 gene, herein designated GAM GENE, and GAM417 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6040] GAM417 gene, herein designated GAM GENE, encodes a GAM417 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM417 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM417 precursor RNA is designated SEQ ID:6514, and is provided hereinbelow with reference to the sequence listing part.

[6041] GAM417 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM417 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6042] An enzyme complex designated DICER COMPLEX, dices the GAM417 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM417 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM417 RNA is designated SEQ ID:6515, and is provided hereinbelow with reference to the sequence listing part.

[6043] GAM417 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM417 target RNA, herein designated GAM TARGET RNA. GAM417 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6044] GAM417 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM417 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM417 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM417 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM417 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6045] The complementary binding of GAM417 RNA, herein designated GAM RNA, to target binding sites on GAM417 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM417 target RNA, herein designated GAM TARGET RNA, into GAM417 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6046] It is appreciated that GAM417 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM417 target genes. The mRNA of each one of this plurality of GAM417 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM417 RNA,

herein designated GAM RNA, and which when bound by GAM417 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM417 target proteins.

[6047] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM417 gene, herein designated GAM GENE, on one or more GAM417 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6048] It is yet further appreciated that specific functions, and accordingly utilities, of GAM417 correlate with, and may be deduced from, the identity of the target genes which

GAM417 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6049] Nucleotide sequences of the GAM417 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM417 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM417 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM417 are further described hereinbelow with reference to Table Table1.

[6050] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM417 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6051]

[6052] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 418 (GAM418) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6053] GAM418 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM418 was detected is described hereinabove with reference to Figs. 2-8.

[6054] GAM418 gene, herein designated GAM GENE, and GAM418 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6055] GAM418 gene, herein designated GAM GENE, encodes a GAM418 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM418 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM418 precursor RNA is designated SEQ ID:6529, and is provided hereinbelow with reference to the sequence listing part.

[6056] GAM418 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM418 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[6057] An enzyme complex designated DICER COMPLEX, dices the GAM418 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM418 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM418 RNA is designated SEQ ID:6530, and is provided hereinbelow with reference to the sequence listing part.

[6058] GAM418 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM418 target RNA, herein designated GAM TARGET RNA. GAM418 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6059] GAM418 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM418 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM418 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM418 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM418 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6060] The complementary binding of GAM418 RNA, herein designated GAM RNA, to target binding sites on GAM418 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM418 target RNA, herein desig-

nated GAM TARGET RNA, into GAM418 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6061] It is appreciated that GAM418 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM418 target genes. The mRNA of each one of this plurality of GAM418 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM418 RNA, herein designated GAM RNA, and which when bound by GAM418 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM418 target proteins.

[6062] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM418 gene, herein designated GAM GENE, on one or more GAM418 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6063] It is yet further appreciated that specific functions, and accordingly utilities, of GAM418 correlate with, and may be deduced from, the identity of the target genes which GAM418 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6064] Nucleotide sequences of the GAM418 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM418 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM418 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM418 are further described hereinbelow with reference to Table Table1.

[6065] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM418 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[6066]

[6067] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 419 (GAM419) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6068] GAM419 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM419 was detected is described hereinabove with reference to Figs. 2-8.

[6069] GAM419 gene, herein designated GAM GENE, and GAM419 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6070] GAM419 gene, herein designated GAM GENE, encodes a GAM419 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM419 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM419 precursor RNA is designated SEQ ID:6547, and is provided hereinbelow with ref-

erence to the sequence listing part.

[6071] GAM419 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM419 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6072] An enzyme complex designated DICER COMPLEX, dices the GAM419 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM419 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 78%) nucleotide sequence of GAM419 RNA is designated SEQ ID:6548, and is provided hereinbelow with reference to the sequence listing part.

[6073] GAM419 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM419 target RNA, herein designated GAM TARGET RNA.

GAM419 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6074] GAM419 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM419 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM419 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM419 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM419 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6075] The complementary binding of GAM419 RNA, herein designated GAM RNA, to target binding sites on GAM419 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM419 target RNA, herein designated GAM TARGET RNA, into GAM419 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6076] It is appreciated that GAM419 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM419 target genes. The mRNA of each one of this plurality of GAM419 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM419 RNA, herein designated GAM RNA, and which when bound by GAM419 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM419 target proteins.

[6077] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM419 gene, herein designated GAM GENE, on one or more GAM419 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6078] It is yet further appreciated that specific functions, and accordingly utilities, of GAM419 correlate with, and may be deduced from, the identity of the target genes which GAM419 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6079] Nucleotide sequences of the GAM419 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM419 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM419 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM419 are further described hereinbelow with reference to Table Table1.

[6080] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM419 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6081]

[6082] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 420 (GAM420) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6083] GAM420 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM420 was detected is described hereinabove with reference to Figs. 2-8.

[6084] GAM420 gene, herein designated GAM GENE, and GAM420 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[6085] GAM420 gene, herein designated GAM GENE, encodes a GAM420 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM420 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM420 precursor RNA is designated SEQ ID:6550, and is provided hereinbelow with reference to the sequence listing part.

[6086] GAM420 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM420 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6087] An enzyme complex designated DICER COMPLEX, dices the GAM420 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM420 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 24%) nucleotide sequence of GAM420 RNA is designated SEQ ID:6551, and is provided hereinbelow with reference to the sequence listing part.

[6088] GAM420 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM420 target RNA, herein designated GAM TARGET RNA. GAM420 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6089] GAM420 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM420 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM420 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM420 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM420 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6090] The complementary binding of GAM420 RNA, herein designated GAM RNA, to target binding sites on GAM420 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM420 target RNA, herein designated GAM TARGET RNA, into GAM420 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6091] It is appreciated that GAM420 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM420 target genes. The mRNA of each one of this plurality of GAM420 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM420 RNA, herein designated GAM RNA, and which when bound by GAM420 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM420 target proteins.

[6092] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM420 gene, herein designated GAM GENE, on one or more GAM420 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[6093] It is yet further appreciated that specific functions, and accordingly utilities, of GAM420 correlate with, and may be deduced from, the identity of the target genes which GAM420 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6094] Nucleotide sequences of the GAM420 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM420 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM420 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM420 are further described hereinbelow with reference to Table Table1.

[6095] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM420 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6096]

[6097] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

421 (GAM421) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6098] GAM421 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM421 was detected is described hereinabove with reference to Figs. 2-8.

[6099] GAM421 gene, herein designated GAM GENE, and GAM421 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6100] GAM421 gene, herein designated GAM GENE, encodes a GAM421 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM421 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM421 precursor RNA is designated SEQ ID:6561, and is provided hereinbelow with reference to the sequence listing part.

[6101] GAM421 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM421 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6102] An enzyme complex designated DICER COMPLEX, dices the GAM421 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM421 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 70%) nucleotide sequence of GAM421 RNA is designated SEQ ID:6562, and is provided hereinbelow with reference to the sequence listing part.

[6103] GAM421 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM421 target RNA, herein designated GAM TARGET RNA. GAM421 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6104] GAM421 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM421 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM421 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM421 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM421 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6105] The complementary binding of GAM421 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM421 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM421 target RNA, herein designated GAM TARGET RNA, into GAM421 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6106] It is appreciated that GAM421 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM421 target genes. The mRNA of each one of this plurality of GAM421 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM421 RNA, herein designated GAM RNA, and which when bound by GAM421 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM421 target proteins.

[6107] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM421 gene, herein designated GAM GENE, on one or more GAM421 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6108] It is yet further appreciated that specific functions, and accordingly utilities, of GAM421 correlate with, and may be deduced from, the identity of the target genes which GAM421 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6109] Nucleotide sequences of the GAM421 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM421 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM421 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM421 are further described hereinbelow with reference to Table Table1.

[6110] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM421 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6111]

[6112] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 422 (GAM422) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6113] GAM422 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM422 was detected is described hereinabove with reference to Figs. 2-8.

[6114] GAM422 gene, herein designated GAM GENE, and GAM422 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6115] GAM422 gene, herein designated GAM GENE, encodes a GAM422 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM422 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM422 precursor RNA is designated SEQ ID:6593, and is provided hereinbelow with reference to the sequence listing part.

[6116] GAM422 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM422 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6117] An enzyme complex designated DICER COMPLEX, dices the GAM422 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM422 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 60%) nucleotide sequence of GAM422 RNA is designated SEQ ID:6594, and is provided hereinbelow with reference to the sequence listing part.

[6118] GAM422 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM422 target RNA, herein designated GAM TARGET RNA. GAM422 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6119] GAM422 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM422 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM422 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM422 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM422 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6120] The complementary binding of GAM422 RNA, herein designated GAM RNA, to target binding sites on GAM422 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM422 target RNA, herein designated GAM TARGET RNA, into GAM422 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6121] It is appreciated that GAM422 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM422 target genes. The mRNA of each one of this plurality of GAM422 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM422 RNA, herein designated GAM RNA, and which when bound by

GAM422 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM422 target proteins.

[6122] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM422 gene, herein designated GAM GENE, on one or more GAM422 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6123] It is yet further appreciated that specific functions, and accordingly utilities, of GAM422 correlate with, and may be deduced from, the identity of the target genes which GAM422 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[6124] Nucleotide sequences of the GAM422 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM422 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM422 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM422 are further described hereinbelow with reference to Table Table1.

[6125] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM422 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6126]

[6127] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 423 (GAM423) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6128] GAM423 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM423 was detected is described hereinabove with reference to Figs. 2-8.

[6129] GAM423 gene, herein designated GAM GENE, and GAM423 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6130] GAM423 gene, herein designated GAM GENE, encodes a GAM423 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM423 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM423 precursor RNA is designated SEQ ID:6611, and is provided hereinbelow with reference to the sequence listing part.

[6131] GAM423 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM423 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6132] An enzyme complex designated DICER COMPLEX, dices the GAM423 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM423 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM423 RNA is designated SEQ ID:6612, and is provided hereinbelow with reference to the sequence listing part.

[6133] GAM423 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM423 target RNA, herein designated GAM TARGET RNA. GAM423 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6134] GAM423 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM423 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM423 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM423 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM423 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6135] The complementary binding of GAM423 RNA, herein designated GAM RNA, to target binding sites on GAM423 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM423 target RNA, herein designated GAM TARGET RNA, into GAM423 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6136] It is appreciated that GAM423 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM423 target genes. The mRNA of each one of this plu-

rality of GAM423 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM423 RNA, herein designated GAM RNA, and which when bound by GAM423 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM423 target proteins.

[6137] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM423 gene, herein designated GAM GENE, on one or more GAM423 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6138] It is yet further appreciated that specific functions, and accordingly utilities, of GAM423 correlate with, and may be deduced from, the identity of the target genes which GAM423 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6139] Nucleotide sequences of the GAM423 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM423 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM423 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM423 are further described hereinbelow with reference to Table Table1.

[6140] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM423 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6141]

[6142] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 424 (GAM424) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[6143] GAM424 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM424 was detected is described hereinabove with reference to Figs. 2-8.

[6144] GAM424 gene, herein designated GAM GENE, and GAM424 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6145] GAM424 gene, herein designated GAM GENE, encodes a GAM424 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM424 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM424 precursor RNA is designated SEQ ID:6623, and is provided hereinbelow with reference to the sequence listing part.

[6146] GAM424 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM424 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6147] An enzyme complex designated DICER COMPLEX, dices the GAM424 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM424 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 20%) nucleotide sequence of GAM424 RNA is designated SEQ ID:6624, and is provided hereinbelow with reference to the sequence listing part.

[6148] GAM424 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM424 target RNA, herein designated GAM TARGET RNA.
GAM424 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[6149] GAM424 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM424 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM424 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM424 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM424 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6150] The complementary binding of GAM424 RNA, herein designated GAM RNA, to target binding sites on GAM424 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM424 target RNA, herein designated GAM TARGET RNA, into GAM424 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6151] It is appreciated that GAM424 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM424 target genes. The mRNA of each one of this plurality of GAM424 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM424 RNA, herein designated GAM RNA, and which when bound by GAM424 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM424 target proteins.

[6152] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM424 gene, herein designated GAM GENE, on one or more GAM424 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6153] It is yet further appreciated that specific functions, and accordingly utilities, of GAM424 correlate with, and may be deduced from, the identity of the target genes which GAM424 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6154] Nucleotide sequences of the GAM424 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM424 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM424 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM424 are further described hereinbelow with reference to Table Table1.

[6155] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM424 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6156]

[6157] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 425 (GAM425) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6158] GAM425 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM425 was detected is described hereinabove with reference to Figs. 2-8.

[6159] GAM425 gene, herein designated GAM GENE, and GAM425 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6160] GAM425 gene, herein designated GAM GENE, encodes a GAM425 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM425 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM425 precursor RNA is designated SEQ ID:6673, and is provided hereinbelow with reference to the sequence listing part.

[6161] GAM425 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM425 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6162] An enzyme complex designated DICER COMPLEX, dices the GAM425 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM425 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of

GAM425 RNA is designated SEQ ID:6674, and is provided hereinbelow with reference to the sequence listing part.

[6163] GAM425 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM425 target RNA, herein designated GAM TARGET RNA. GAM425 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6164] GAM425 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM425 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM425 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM425 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM425 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6165] The complementary binding of GAM425 RNA, herein designated GAM RNA, to target binding sites on GAM425 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM425 target RNA, herein designated GAM TARGET RNA, into GAM425 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6166] It is appreciated that GAM425 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM425 target genes. The mRNA of each one of this plurality of GAM425 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM425 RNA, herein designated GAM RNA, and which when bound by GAM425 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM425 target proteins.

[6167] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM425 gene, herein designated GAM GENE, on one or more GAM425 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6168] It is yet further appreciated that specific functions, and accordingly utilities, of GAM425 correlate with, and may be deduced from, the identity of the target genes which GAM425 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6169] Nucleotide sequences of the GAM425 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM425 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM425 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM425 are further described hereinbelow with reference to Table Table1.

[6170] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM425 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6171]

[6172] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 426 (GAM426) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6173] GAM426 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM426 was detected is described hereinabove

with reference to Figs. 2-8.

[6174] GAM426 gene, herein designated GAM GENE, and GAM426 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6175] GAM426 gene, herein designated GAM GENE, encodes a GAM426 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM426 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM426 precursor RNA is designated SEQ ID:6679, and is provided hereinbelow with reference to the sequence listing part.

[6176] GAM426 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM426 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6177] An enzyme complex designated DICER COMPLEX, dices the GAM426 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM426 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 50%) nucleotide sequence of GAM426 RNA is designated SEQ ID:6680, and is provided hereinbelow with reference to the sequence listing part.

[6178] GAM426 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM426 target RNA, herein designated GAM TARGET RNA. GAM426 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6179] GAM426 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM426 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM426 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM426 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM426 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6180] The complementary binding of GAM426 RNA, herein designated GAM RNA, to target binding sites on GAM426 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM426 target RNA, herein designated GAM TARGET RNA, into GAM426 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[6181] It is appreciated that GAM426 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM426 target genes. The mRNA of each one of this plurality of GAM426 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM426 RNA, herein designated GAM RNA, and which when bound by GAM426 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM426 target proteins.

[6182] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM426 gene, herein designated GAM GENE, on one or more GAM426 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6183] It is yet further appreciated that specific functions, and accordingly utilities, of GAM426 correlate with, and may be deduced from, the identity of the target genes which GAM426 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6184] Nucleotide sequences of the GAM426 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM426 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM426 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM426 are further described hereinbelow with reference to Table Table1.

[6185] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM426 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6186]

[6187] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 427 (GAM427) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6188] GAM427 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM427 was detected is described hereinabove with reference to Figs. 2-8.

[6189] GAM427 gene, herein designated GAM GENE, and GAM427 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6190] GAM427 gene, herein designated GAM GENE, encodes a GAM427 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM427 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM427 precursor RNA is designated SEQ ID:6693, and is provided hereinbelow with reference to the sequence listing part.

[6191] GAM427 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM427 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6192] An enzyme complex designated DICER COMPLEX, dices the GAM427 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM427 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM427 RNA is designated SEQ ID:6694, and is provided hereinbelow with reference to the sequence listing part.

[6193] GAM427 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM427 target RNA, herein designated GAM TARGET RNA.

GAM427 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6194] GAM427 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM427 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM427 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM427 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM427 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6195] The complementary binding of GAM427 RNA, herein designated GAM RNA, to target binding sites on GAM427 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM427 target RNA, herein designated GAM TARGET RNA, into GAM427 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6196] It is appreciated that GAM427 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM427 target genes. The mRNA of each one of this plurality of GAM427 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM427 RNA, herein designated GAM RNA, and which when bound by GAM427 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM427 target proteins.

[6197] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM427 gene, herein designated GAM GENE, on one or more GAM427 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6198] It is yet further appreciated that specific functions, and accordingly utilities, of GAM427 correlate with, and may be deduced from, the identity of the target genes which GAM427 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6199] Nucleotide sequences of the GAM427 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM427 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM427 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM427 are further described hereinbelow with reference to Table Table1.

[6200] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM427 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6201]

[6202] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 428 (GAM428) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6203] GAM428 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM428 was detected is described hereinabove with reference to Figs. 2-8.

[6204] GAM428 gene, herein designated GAM GENE, and GAM428 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6205] GAM428 gene, herein designated GAM GENE, encodes a

GAM428 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM428 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM428 precursor RNA is designated SEQ ID:6716, and is provided hereinbelow with reference to the sequence listing part.

[6206] GAM428 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM428 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6207] An enzyme complex designated DICER COMPLEX, dices the GAM428 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM428 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 73%) nucleotide sequence of GAM428 RNA is designated SEQ ID:6717, and is provided hereinbelow with reference to the sequence listing part.

[6208] GAM428 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM428 target RNA, herein designated GAM TARGET RNA. GAM428 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6209] GAM428 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM428 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM428 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM428 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM428 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6210] The complementary binding of GAM428 RNA, herein designated GAM RNA, to target binding sites on GAM428 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM428 target RNA, herein designated GAM TARGET RNA, into GAM428 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6211] It is appreciated that GAM428 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM428 target genes. The mRNA of each one of this plurality of GAM428 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM428 RNA, herein designated GAM RNA, and which when bound by GAM428 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM428 target proteins.

[6212] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM428 gene, herein designated GAM GENE, on one or more GAM428 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6213] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM428 correlate with, and may be deduced from, the identity of the target genes which GAM428 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6214] Nucleotide sequences of the GAM428 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM428 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM428 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM428 are further described hereinbelow with reference to Table Table1.

[6215] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM428 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6216]

[6217] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 429 (GAM429) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[6218] GAM429 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM429 was detected is described hereinabove with reference to Figs. 2-8.

[6219] GAM429 gene, herein designated GAM GENE, and GAM429 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6220] GAM429 gene, herein designated GAM GENE, encodes a GAM429 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM429 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM429 precursor RNA is designated SEQ ID:6729, and is provided hereinbelow with reference to the sequence listing part.

[6221] GAM429 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM429 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6222] An enzyme complex designated DICER COMPLEX, dices the GAM429 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM429 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM429 RNA is designated SEQ ID:6730, and is provided hereinbelow with reference to the sequence listing part.

[6223] GAM429 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM429 target RNA, herein designated GAM TARGET RNA.
GAM429 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6224] GAM429 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM429 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM429 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM429 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM429 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6225] The complementary binding of GAM429 RNA, herein designated GAM RNA, to target binding sites on GAM429 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM429 target RNA, herein designated GAM TARGET RNA, into GAM429 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6226] It is appreciated that GAM429 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM429 target genes. The mRNA of each one of this plurality of GAM429 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM429 RNA, herein designated GAM RNA, and which when bound by GAM429 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM429 target proteins.

[6227] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM429 gene, herein designated GAM GENE, on one or more GAM429 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6228] It is yet further appreciated that specific functions, and accordingly utilities, of GAM429 correlate with, and may be deduced from, the identity of the target genes which GAM429 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6229] Nucleotide sequences of the GAM429 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM429 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM429 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM429 are further described hereinbelow with reference to Table Table1.

[6230] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM429 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6231]

[6232] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 430 (GAM430) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6233] GAM430 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM430 was detected is described hereinabove with reference to Figs. 2-8.

[6234] GAM430 gene, herein designated GAM GENE, and GAM430 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6235] GAM430 gene, herein designated GAM GENE, encodes a GAM430 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM430 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM430 precursor RNA is designated SEQ ID:6752, and is provided hereinbelow with reference to the sequence listing part.

[6236] GAM430 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM430 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6237] An enzyme complex designated DICER COMPLEX, dices the GAM430 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM430 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM430 RNA is designated SEQ ID:6753, and is provided

hereinbelow with reference to the sequence listing part.

[6238] GAM430 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM430 target RNA, herein designated GAM TARGET RNA.
GAM430 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6239] GAM430 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM430 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM430 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM430 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM430 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6240] The complementary binding of GAM430 RNA, herein designated GAM RNA, to target binding sites on GAM430 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM430 target RNA, herein designated GAM TARGET RNA, into GAM430 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6241] It is appreciated that GAM430 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM430 target genes. The mRNA of each one of this plurality of GAM430 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM430 RNA, herein designated GAM RNA, and which when bound by GAM430 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM430 tar-

get proteins.

[6242] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM430 gene, herein designated GAM GENE, on one or more GAM430 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6243] It is yet further appreciated that specific functions, and accordingly utilities, of GAM430 correlate with, and may be deduced from, the identity of the target genes which GAM430 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6244] Nucleotide sequences of the GAM430 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM430 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM430 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM430 are further described hereinbelow with reference to Table Table1.

[6245] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM430 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6246]

[6247] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 431 (GAM431) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6248] GAM431 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM431 was detected is described hereinabove with reference to Figs. 2-8.

[6249] GAM431 gene, herein designated GAM GENE, and GAM431 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6250] GAM431 gene, herein designated GAM GENE, encodes a GAM431 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM431 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM431 precursor RNA is designated SEQ ID:6759, and is provided hereinbelow with reference to the sequence listing part.

[6251] GAM431 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM431 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6252] An enzyme complex designated DICER COMPLEX, dices

the GAM431 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM431 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 73%) nucleotide sequence of GAM431 RNA is designated SEQ ID:6760, and is provided hereinbelow with reference to the sequence listing part.

[6253] GAM431 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM431 target RNA, herein designated GAM TARGET RNA. GAM431 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6254] GAM431 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM431 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM431

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM431 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM431 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6255] The complementary binding of GAM431 RNA, herein designated GAM RNA, to target binding sites on GAM431 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM431 target RNA, herein designated GAM TARGET RNA, into GAM431 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6256] It is appreciated that GAM431 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM431 target genes. The mRNA of each one of this plurality of GAM431 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM431 RNA, herein designated GAM RNA, and which when bound by GAM431 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM431 target proteins.

[6257] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM431 gene, herein designated GAM GENE, on one or more GAM431 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6258] It is yet further appreciated that specific functions, and accordingly utilities, of GAM431 correlate with, and may be deduced from, the identity of the target genes which GAM431 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6259] Nucleotide sequences of the GAM431 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM431 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM431 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM431 are further described hereinbelow with reference to Table Table1.

[6260] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM431 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6261]

[6262] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 432 (GAM432) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6263] GAM432 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM432 was detected is described hereinabove with reference to Figs. 2-8.

[6264] GAM432 gene, herein designated GAM GENE, and GAM432 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6265] GAM432 gene, herein designated GAM GENE, encodes a GAM432 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM432 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM432 precursor RNA is designated SEQ ID:6766, and is provided hereinbelow with reference to the sequence listing part.

[6266] GAM432 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM432 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6267] An enzyme complex designated DICER COMPLEX, dices the GAM432 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM432 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 36%) nucleotide sequence of GAM432 RNA is designated SEQ ID:6767, and is provided hereinbelow with reference to the sequence listing part.

[6268] GAM432 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM432 target RNA, herein designated GAM TARGET RNA. GAM432 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6269] GAM432 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM432 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM432 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM432 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM432 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[6270] The complementary binding of GAM432 RNA, herein designated GAM RNA, to target binding sites on GAM432 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM432 target RNA, herein designated GAM TARGET RNA, into GAM432 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6271] It is appreciated that GAM432 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM432 target genes. The mRNA of each one of this plurality of GAM432 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM432 RNA, herein designated GAM RNA, and which when bound by GAM432 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM432 target proteins.

[6272] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM432 gene, herein designated GAM GENE, on one or

more GAM432 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6273] It is yet further appreciated that specific functions, and accordingly utilities, of GAM432 correlate with, and may be deduced from, the identity of the target genes which GAM432 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6274] Nucleotide sequences of the GAM432 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM432 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM432 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM432 are further de-

scribed hereinbelow with reference to Table Table1.

[6275] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM432 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6276]

[6277] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 433 (GAM433) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6278] GAM433 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM433 was detected is described hereinabove with reference to Figs. 2-8.

[6279] GAM433 gene, herein designated GAM GENE, and GAM433 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6280] GAM433 gene, herein designated GAM GENE, encodes a GAM433 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM433 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM433 precursor RNA is designated SEQ ID:6788, and is provided hereinbelow with reference to the sequence listing part.

[6281] GAM433 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM433 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6282] An enzyme complex designated DICER COMPLEX, dices the GAM433 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM433 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM433 RNA is designated SEQ ID:6789, and is provided hereinbelow with reference to the sequence listing part.

[6283] GAM433 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM433 target RNA, herein designated GAM TARGET RNA. GAM433 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6284] GAM433 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM433 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM433 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM433 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM433 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6285] The complementary binding of GAM433 RNA, herein designated GAM RNA, to target binding sites on GAM433 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM433 target RNA, herein designated GAM TARGET RNA, into GAM433 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6286] It is appreciated that GAM433 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM433 target genes. The mRNA of each one of this plurality of GAM433 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM433 RNA, herein designated GAM RNA, and which when bound by GAM433 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM433 target proteins.

[6287] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM433 gene, herein designated GAM GENE, on one or more GAM433 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6288] It is yet further appreciated that specific functions, and accordingly utilities, of GAM433 correlate with, and may

be deduced from, the identity of the target genes which GAM433 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6289] Nucleotide sequences of the GAM433 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM433 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM433 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM433 are further described hereinbelow with reference to Table Table1.

[6290] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM433 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6291]

[6292] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 434 (GAM434) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6293] GAM434 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM434 was detected is described hereinabove with reference to Figs. 2-8.

[6294] GAM434 gene, herein designated GAM GENE, and GAM434 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6295] GAM434 gene, herein designated GAM GENE, encodes a GAM434 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM434 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM434 precursor RNA is designated SEQ ID:6806, and is provided hereinbelow with reference to the sequence listing part.

[6296] GAM434 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM434 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6297] An enzyme complex designated DICER COMPLEX, dices the GAM434 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM434 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM434 RNA is designated SEQ ID:6807, and is provided hereinbelow with reference to the sequence listing part.

[6298] GAM434 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM434 target RNA, herein designated GAM TARGET RNA. GAM434 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6299] GAM434 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM434 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM434 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM434 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM434 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6300] The complementary binding of GAM434 RNA, herein designated GAM RNA, to target binding sites on GAM434 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM434 target RNA, herein designated GAM TARGET RNA, into GAM434 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6301] It is appreciated that GAM434 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM434 target genes. The mRNA of each one of this plurality of GAM434 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM434 RNA, herein designated GAM RNA, and which when bound by GAM434 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM434 target proteins.

[6302] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM434 gene, herein designated GAM GENE, on one or more GAM434 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6303] It is yet further appreciated that specific functions, and accordingly utilities, of GAM434 correlate with, and may be deduced from, the identity of the target genes which GAM434 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6304] Nucleotide sequences of the GAM434 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM434 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM434 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM434 are further described hereinbelow with reference to Table Table1.

[6305] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM434 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6306]

[6307] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 435 (GAM435) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6308] GAM435 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM435 was detected is described hereinabove with reference to Figs. 2-8.

[6309] GAM435 gene, herein designated GAM GENE, and GAM435 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6310] GAM435 gene, herein designated GAM GENE, encodes a GAM435 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM435 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM435 precursor RNA is desig-

nated SEQ ID:6817, and is provided hereinbelow with reference to the sequence listing part.

[6311] GAM435 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM435 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6312] An enzyme complex designated DICER COMPLEX, dices the GAM435 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM435 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM435 RNA is designated SEQ ID:6818, and is provided hereinbelow with reference to the sequence listing part.

[6313] GAM435 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM435 target RNA, herein designated GAM TARGET RNA. GAM435 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6314] GAM435 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM435 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM435 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM435 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM435

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6315] The complementary binding of GAM435 RNA, herein designated GAM RNA, to target binding sites on GAM435 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM435 target RNA, herein designated GAM TARGET RNA, into GAM435 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6316] It is appreciated that GAM435 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM435 target genes. The mRNA of each one of this plurality of GAM435 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM435 RNA, herein designated GAM RNA, and which when bound by GAM435 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM435 target proteins.

[6317] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM435 gene, herein designated GAM GENE, on one or more GAM435 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6318] It is yet further appreciated that specific functions, and accordingly utilities, of GAM435 correlate with, and may be deduced from, the identity of the target genes which GAM435 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6319] Nucleotide sequences of the GAM435 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM435 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM435 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM435 are further described hereinbelow with reference to Table Table1.

[6320] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM435 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6321]

[6322] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 436 (GAM436) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6323] GAM436 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM436 was detected is described hereinabove with reference to Figs. 2-8.

[6324] GAM436 gene, herein designated GAM GENE, and

GAM436 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6325] GAM436 gene, herein designated GAM GENE, encodes a GAM436 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM436 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM436 precursor RNA is designated SEQ ID:6826, and is provided hereinbelow with reference to the sequence listing part.

[6326] GAM436 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM436 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6327] An enzyme complex designated DICER COMPLEX, dices the GAM436 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM436 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM436 RNA is designated SEQ ID:6827, and is provided hereinbelow with reference to the sequence listing part.

[6328] GAM436 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM436 target RNA, herein designated GAM TARGET RNA. GAM436 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6329] GAM436 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM436 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM436 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM436 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM436 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6330] The complementary binding of GAM436 RNA, herein designated GAM RNA, to target binding sites on GAM436 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM436 target RNA, herein designated GAM TARGET RNA, into GAM436 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6331] It is appreciated that GAM436 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM436 target genes. The mRNA of each one of this plurality of GAM436 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM436 RNA, herein designated GAM RNA, and which when bound by GAM436 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM436 target proteins.

[6332] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM436 gene, herein designated GAM GENE, on one or more GAM436 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6333] It is yet further appreciated that specific functions, and accordingly utilities, of GAM436 correlate with, and may be deduced from, the identity of the target genes which GAM436 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6334] Nucleotide sequences of the GAM436 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM436 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM436 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM436 are further described hereinbelow with reference to Table Table1.

[6335] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM436 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6336]

[6337] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 437 (GAM437) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6338] GAM437 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM437 was detected is described hereinabove with reference to Figs. 2-8.

[6339] GAM437 gene, herein designated GAM GENE, and GAM437 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6340] GAM437 gene, herein designated GAM GENE, encodes a GAM437 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM437 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM437 precursor RNA is designated SEQ ID:6856, and is provided hereinbelow with reference to the sequence listing part.

[6341] GAM437 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM437 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6342] An enzyme complex designated DICER COMPLEX, dices the GAM437 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM437 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM437 RNA is designated SEQ ID:6857, and is provided hereinbelow with reference to the sequence listing part.

[6343] GAM437 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM437 target RNA, herein designated GAM TARGET RNA. GAM437 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6344] GAM437 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM437 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM437 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM437 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM437 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6345] The complementary binding of GAM437 RNA, herein designated GAM RNA, to target binding sites on GAM437 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM437 target RNA, herein designated GAM TARGET RNA, into GAM437 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6346] It is appreciated that GAM437 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM437 target genes. The mRNA of each one of this plurality of GAM437 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM437 RNA, herein designated GAM RNA, and which when bound by GAM437 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM437 target proteins.

[6347] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM437 gene, herein designated GAM GENE, on one or more GAM437 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6348] It is yet further appreciated that specific functions, and accordingly utilities, of GAM437 correlate with, and may be deduced from, the identity of the target genes which GAM437 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6349] Nucleotide sequences of the GAM437 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM437 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM437 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM437 are further described hereinbelow with reference to Table Table1.

[6350] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM437 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6351]

[6352] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 438 (GAM438) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6353] GAM438 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM438 was detected is described hereinabove with reference to Figs. 2-8.

[6354] GAM438 gene, herein designated GAM GENE, and GAM438 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6355] GAM438 gene, herein designated GAM GENE, encodes a GAM438 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM438 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM438 precursor RNA is designated SEQ ID:6869, and is provided hereinbelow with reference to the sequence listing part.

[6356] GAM438 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM438 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6357] An enzyme complex designated DICER COMPLEX, dices the GAM438 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM438 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 29%) nucleotide sequence of GAM438 RNA is designated SEQ ID:6870, and is provided hereinbelow with reference to the sequence listing part.

[6358] GAM438 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM438 target RNA, herein designated GAM TARGET RNA. GAM438 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6359] GAM438 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM438 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM438 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM438 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM438 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6360] The complementary binding of GAM438 RNA, herein designated GAM RNA, to target binding sites on GAM438 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM438 target RNA, herein designated GAM TARGET RNA, into GAM438 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6361] It is appreciated that GAM438 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM438 target genes. The mRNA of each one of this plurality of GAM438 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM438 RNA,

herein designated GAM RNA, and which when bound by GAM438 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM438 target proteins.

[6362] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM438 gene, herein designated GAM GENE, on one or more GAM438 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6363] It is yet further appreciated that specific functions, and accordingly utilities, of GAM438 correlate with, and may be deduced from, the identity of the target genes which

GAM438 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6364] Nucleotide sequences of the GAM438 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM438 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM438 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM438 are further described hereinbelow with reference to Table Table1.

[6365] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM438 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6366]

[6367] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 439 (GAM439) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6368] GAM439 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM439 was detected is described hereinabove with reference to Figs. 2-8.

[6369] GAM439 gene, herein designated GAM GENE, and GAM439 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6370] GAM439 gene, herein designated GAM GENE, encodes a GAM439 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM439 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM439 precursor RNA is designated SEQ ID:6887, and is provided hereinbelow with reference to the sequence listing part.

[6371] GAM439 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM439 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[6372] An enzyme complex designated DICER COMPLEX, dices the GAM439 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM439 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM439 RNA is designated SEQ ID:6888, and is provided hereinbelow with reference to the sequence listing part.

[6373] GAM439 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM439 target RNA, herein designated GAM TARGET RNA.
GAM439 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6374] GAM439 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM439 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM439 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM439 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM439 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6375] The complementary binding of GAM439 RNA, herein designated GAM RNA, to target binding sites on GAM439 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM439 target RNA, herein desig-

nated GAM TARGET RNA, into GAM439 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6376] It is appreciated that GAM439 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM439 target genes. The mRNA of each one of this plurality of GAM439 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM439 RNA, herein designated GAM RNA, and which when bound by GAM439 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM439 target proteins.

[6377] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM439 gene, herein designated GAM GENE, on one or more GAM439 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6378] It is yet further appreciated that specific functions, and accordingly utilities, of GAM439 correlate with, and may be deduced from, the identity of the target genes which GAM439 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6379] Nucleotide sequences of the GAM439 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM439 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM439 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM439 are further described hereinbelow with reference to Table Table1.

[6380] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM439 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[6381]

[6382] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 440 (GAM440) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6383] GAM440 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM440 was detected is described hereinabove with reference to Figs. 2-8.

[6384] GAM440 gene, herein designated GAM GENE, and GAM440 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6385] GAM440 gene, herein designated GAM GENE, encodes a GAM440 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM440 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM440 precursor RNA is designated SEQ ID:6903, and is provided hereinbelow with ref-

erence to the sequence listing part.

[6386] GAM440 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM440 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6387] An enzyme complex designated DICER COMPLEX, dices the GAM440 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM440 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM440 RNA is designated SEQ ID:6904, and is provided hereinbelow with reference to the sequence listing part.

[6388] GAM440 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM440 target RNA, herein designated GAM TARGET RNA.

GAM440 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6389] GAM440 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM440 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM440 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM440 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM440 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6390] The complementary binding of GAM440 RNA, herein designated GAM RNA, to target binding sites on GAM440 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM440 target RNA, herein designated GAM TARGET RNA, into GAM440 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6391] It is appreciated that GAM440 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM440 target genes. The mRNA of each one of this plurality of GAM440 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM440 RNA, herein designated GAM RNA, and which when bound by GAM440 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM440 target proteins.

[6392] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM440 gene, herein designated GAM GENE, on one or more GAM440 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6393] It is yet further appreciated that specific functions, and accordingly utilities, of GAM440 correlate with, and may be deduced from, the identity of the target genes which GAM440 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6394] Nucleotide sequences of the GAM440 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM440 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM440 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM440 are further described hereinbelow with reference to Table Table1.

[6395] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM440 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6396]

[6397] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 441 (GAM441) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6398] GAM441 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM441 was detected is described hereinabove with reference to Figs. 2-8.

[6399] GAM441 gene, herein designated GAM GENE, and GAM441 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[6400] GAM441 gene, herein designated GAM GENE, encodes a GAM441 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM441 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM441 precursor RNA is designated SEQ ID:6916, and is provided hereinbelow with reference to the sequence listing part.

[6401] GAM441 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM441 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6402] An enzyme complex designated DICER COMPLEX, dices the GAM441 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM441 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 76%) nucleotide sequence of GAM441 RNA is designated SEQ ID:6917, and is provided hereinbelow with reference to the sequence listing part.

[6403] GAM441 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM441 target RNA, herein designated GAM TARGET RNA. GAM441 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6404] GAM441 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM441 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM441 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM441 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM441 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6405] The complementary binding of GAM441 RNA, herein designated GAM RNA, to target binding sites on GAM441 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM441 target RNA, herein designated GAM TARGET RNA, into GAM441 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6406] It is appreciated that GAM441 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM441 target genes. The mRNA of each one of this plurality of GAM441 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM441 RNA, herein designated GAM RNA, and which when bound by GAM441 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM441 target proteins.

[6407] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM441 gene, herein designated GAM GENE, on one or more GAM441 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[6408] It is yet further appreciated that specific functions, and accordingly utilities, of GAM441 correlate with, and may be deduced from, the identity of the target genes which GAM441 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6409] Nucleotide sequences of the GAM441 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM441 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM441 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM441 are further described hereinbelow with reference to Table Table1.

[6410] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM441 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6411]

[6412] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

442 (GAM442) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6413] GAM442 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM442 was detected is described hereinabove with reference to Figs. 2-8.

[6414] GAM442 gene, herein designated GAM GENE, and GAM442 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6415] GAM442 gene, herein designated GAM GENE, encodes a GAM442 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM442 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM442 precursor RNA is designated SEQ ID:6920, and is provided hereinbelow with reference to the sequence listing part.

[6416] GAM442 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM442 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6417] An enzyme complex designated DICER COMPLEX, dices the GAM442 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM442 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM442 RNA is designated SEQ ID:6921, and is provided hereinbelow with reference to the sequence listing part.

[6418] GAM442 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM442 target RNA, herein designated GAM TARGET RNA. GAM442 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6419] GAM442 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM442 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM442 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM442 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM442 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6420] The complementary binding of GAM442 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM442 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM442 target RNA, herein designated GAM TARGET RNA, into GAM442 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6421] It is appreciated that GAM442 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM442 target genes. The mRNA of each one of this plurality of GAM442 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM442 RNA, herein designated GAM RNA, and which when bound by GAM442 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM442 target proteins.

[6422] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM442 gene, herein designated GAM GENE, on one or more GAM442 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6423] It is yet further appreciated that specific functions, and accordingly utilities, of GAM442 correlate with, and may be deduced from, the identity of the target genes which GAM442 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6424] Nucleotide sequences of the GAM442 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM442 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM442 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM442 are further described hereinbelow with reference to Table Table1.

[6425] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM442 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6426]

[6427] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 443 (GAM443) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6428] GAM443 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM443 was detected is described hereinabove with reference to Figs. 2-8.

[6429] GAM443 gene, herein designated GAM GENE, and GAM443 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6430] GAM443 gene, herein designated GAM GENE, encodes a GAM443 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM443 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM443 precursor RNA is designated SEQ ID:6933, and is provided hereinbelow with reference to the sequence listing part.

[6431] GAM443 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM443 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6432] An enzyme complex designated DICER COMPLEX, dices the GAM443 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM443 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 62%) nucleotide sequence of GAM443 RNA is designated SEQ ID:6934, and is provided hereinbelow with reference to the sequence listing part.

[6433] GAM443 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM443 target RNA, herein designated GAM TARGET RNA. GAM443 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6434] GAM443 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM443 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM443 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM443 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM443 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6435] The complementary binding of GAM443 RNA, herein designated GAM RNA, to target binding sites on GAM443 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM443 target RNA, herein designated GAM TARGET RNA, into GAM443 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6436] It is appreciated that GAM443 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM443 target genes. The mRNA of each one of this plurality of GAM443 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM443 RNA, herein designated GAM RNA, and which when bound by

GAM443 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM443 target proteins.

[6437] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM443 gene, herein designated GAM GENE, on one or more GAM443 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6438] It is yet further appreciated that specific functions, and accordingly utilities, of GAM443 correlate with, and may be deduced from, the identity of the target genes which GAM443 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[6439] Nucleotide sequences of the GAM443 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM443 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM443 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM443 are further described hereinbelow with reference to Table Table1.

[6440] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM443 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6441]

[6442] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 444 (GAM444) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6443] GAM444 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM444 was detected is described hereinabove with reference to Figs. 2-8.

[6444] GAM444 gene, herein designated GAM GENE, and GAM444 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6445] GAM444 gene, herein designated GAM GENE, encodes a GAM444 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM444 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM444 precursor RNA is designated SEQ ID:6946, and is provided hereinbelow with reference to the sequence listing part.

[6446] GAM444 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM444 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[6447] An enzyme complex designated DICER COMPLEX, dices the GAM444 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM444 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM444 RNA is designated SEQ ID:6947, and is provided hereinbelow with reference to the sequence listing part.

[6448] GAM444 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM444 target RNA, herein designated GAM TARGET RNA. GAM444 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6449] GAM444 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM444 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM444 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM444 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM444 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6450] The complementary binding of GAM444 RNA, herein designated GAM RNA, to target binding sites on GAM444 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM444 target RNA, herein designated GAM TARGET RNA, into GAM444 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6451] It is appreciated that GAM444 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM444 target genes. The mRNA of each one of this plurality of GAM444 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM444 RNA, herein designated GAM RNA, and which when bound by GAM444 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM444 target proteins.

[6452] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM444 gene, herein designated GAM GENE, on one or more GAM444 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6453] It is yet further appreciated that specific functions, and accordingly utilities, of GAM444 correlate with, and may be deduced from, the identity of the target genes which GAM444 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6454] Nucleotide sequences of the GAM444 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM444 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM444 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM444 are further described hereinbelow with reference to Table Table1.

[6455] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM444 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6456]

[6457] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 445 (GAM445) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6458] GAM445 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM445 was detected is described hereinabove with reference to Figs. 2-8.

[6459] GAM445 gene, herein designated GAM GENE, and GAM445 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6460] GAM445 gene, herein designated GAM GENE, encodes a GAM445 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM445 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM445 precursor RNA is designated SEQ ID:6957, and is provided hereinbelow with reference to the sequence listing part.

[6461] GAM445 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM445 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6462] An enzyme complex designated DICER COMPLEX, dices the GAM445 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM445 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM445 RNA is designated SEQ ID:6958, and is provided hereinbelow with reference to the sequence listing part.

[6463] GAM445 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM445

target RNA, herein designated GAM TARGET RNA.

GAM445 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6464] GAM445 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM445 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM445 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM445 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM445 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6465] The complementary binding of GAM445 RNA, herein designated GAM RNA, to target binding sites on GAM445 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM445 target RNA, herein designated GAM TARGET RNA, into GAM445 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6466] It is appreciated that GAM445 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM445 target genes. The mRNA of each one of this plurality of GAM445 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM445 RNA, herein designated GAM RNA, and which when bound by GAM445 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM445 target proteins.

[6467] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM445 gene, herein designated GAM GENE, on one or more GAM445 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6468] It is yet further appreciated that specific functions, and accordingly utilities, of GAM445 correlate with, and may be deduced from, the identity of the target genes which GAM445 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6469] Nucleotide sequences of the GAM445 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM445 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM445 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM445 are further described hereinbelow with reference to Table Table1.

[6470] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM445 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6471]

[6472] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 446 (GAM446) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6473] GAM446 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM446 was detected is described hereinabove with reference to Figs. 2-8.

[6474] GAM446 gene, herein designated GAM GENE, and GAM446 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6475] GAM446 gene, herein designated GAM GENE, encodes a GAM446 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM446 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM446 precursor RNA is designated SEQ ID:6982, and is provided hereinbelow with reference to the sequence listing part.

[6476] GAM446 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM446 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6477] An enzyme complex designated DICER COMPLEX, dices the GAM446 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM446 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM446 RNA is designated SEQ ID:6983, and is provided hereinbelow with reference to the sequence listing part.

[6478] GAM446 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM446 target RNA, herein designated GAM TARGET RNA. GAM446 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6479] GAM446 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM446 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM446 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM446 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM446 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6480] The complementary binding of GAM446 RNA, herein designated GAM RNA, to target binding sites on GAM446 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM446 target RNA, herein designated GAM TARGET RNA, into GAM446 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6481] It is appreciated that GAM446 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM446 target genes. The mRNA of each one of this plu-

rality of GAM446 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM446 RNA, herein designated GAM RNA, and which when bound by GAM446 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM446 target proteins.

[6482] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM446 gene, herein designated GAM GENE, on one or more GAM446 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6483] It is yet further appreciated that specific functions, and accordingly utilities, of GAM446 correlate with, and may be deduced from, the identity of the target genes which GAM446 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6484] Nucleotide sequences of the GAM446 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM446 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM446 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM446 are further described hereinbelow with reference to Table Table1.

[6485] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM446 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6486]

[6487] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 447 (GAM447) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[6488] GAM447 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM447 was detected is described hereinabove with reference to Figs. 2-8.

[6489] GAM447 gene, herein designated GAM GENE, and GAM447 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6490] GAM447 gene, herein designated GAM GENE, encodes a GAM447 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM447 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM447 precursor RNA is designated SEQ ID:7008, and is provided hereinbelow with reference to the sequence listing part.

[6491] GAM447 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM447 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6492] An enzyme complex designated DICER COMPLEX, dices the GAM447 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM447 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM447 RNA is designated SEQ ID:7009, and is provided hereinbelow with reference to the sequence listing part.

[6493] GAM447 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM447 target RNA, herein designated GAM TARGET RNA.
GAM447 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[6494] GAM447 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM447 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM447 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM447 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM447 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6495] The complementary binding of GAM447 RNA, herein designated GAM RNA, to target binding sites on GAM447 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM447 target RNA, herein designated GAM TARGET RNA, into GAM447 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6496] It is appreciated that GAM447 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM447 target genes. The mRNA of each one of this plurality of GAM447 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM447 RNA, herein designated GAM RNA, and which when bound by GAM447 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM447 target proteins.

[6497] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM447 gene, herein designated GAM GENE, on one or more GAM447 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6498] It is yet further appreciated that specific functions, and accordingly utilities, of GAM447 correlate with, and may be deduced from, the identity of the target genes which GAM447 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6499] Nucleotide sequences of the GAM447 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM447 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM447 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM447 are further described hereinbelow with reference to Table Table1.

[6500] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM447 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6501]

[6502] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 448 (GAM448) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6503] GAM448 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM448 was detected is described hereinabove with reference to Figs. 2-8.

[6504] GAM448 gene, herein designated GAM GENE, and GAM448 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6505] GAM448 gene, herein designated GAM GENE, encodes a GAM448 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM448 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM448 precursor RNA is designated SEQ ID:7057, and is provided hereinbelow with reference to the sequence listing part.

[6506] GAM448 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM448 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6507] An enzyme complex designated DICER COMPLEX, dices the GAM448 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM448 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 50%) nucleotide sequence of

GAM448 RNA is designated SEQ ID:7009, and is provided hereinbelow with reference to the sequence listing part.

[6508] GAM448 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM448 target RNA, herein designated GAM TARGET RNA. GAM448 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6509] GAM448 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM448 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM448 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM448 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM448 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6510] The complementary binding of GAM448 RNA, herein designated GAM RNA, to target binding sites on GAM448 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM448 target RNA, herein designated GAM TARGET RNA, into GAM448 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6511] It is appreciated that GAM448 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM448 target genes. The mRNA of each one of this plurality of GAM448 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM448 RNA, herein designated GAM RNA, and which when bound by GAM448 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM448 target proteins.

[6512] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM448 gene, herein designated GAM GENE, on one or more GAM448 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6513] It is yet further appreciated that specific functions, and accordingly utilities, of GAM448 correlate with, and may be deduced from, the identity of the target genes which GAM448 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6514] Nucleotide sequences of the GAM448 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM448 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM448 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM448 are further described hereinbelow with reference to Table Table1.

[6515] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM448 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6516]

[6517] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 449 (GAM449) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6518] GAM449 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM449 was detected is described hereinabove

with reference to Figs. 2-8.

[6519] GAM449 gene, herein designated GAM GENE, and GAM449 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6520] GAM449 gene, herein designated GAM GENE, encodes a GAM449 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM449 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM449 precursor RNA is designated SEQ ID:7061, and is provided hereinbelow with reference to the sequence listing part.

[6521] GAM449 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM449 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6522] An enzyme complex designated DICER COMPLEX, dices the GAM449 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM449 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM449 RNA is designated SEQ ID:7062, and is provided hereinbelow with reference to the sequence listing part.

[6523] GAM449 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM449 target RNA, herein designated GAM TARGET RNA. GAM449 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6524] GAM449 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM449 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM449 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM449 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM449 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6525] The complementary binding of GAM449 RNA, herein designated GAM RNA, to target binding sites on GAM449 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM449 target RNA, herein designated GAM TARGET RNA, into GAM449 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[6526] It is appreciated that GAM449 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM449 target genes. The mRNA of each one of this plurality of GAM449 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM449 RNA, herein designated GAM RNA, and which when bound by GAM449 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM449 target proteins.

[6527] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM449 gene, herein designated GAM GENE, on one or more GAM449 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6528] It is yet further appreciated that specific functions, and accordingly utilities, of GAM449 correlate with, and may be deduced from, the identity of the target genes which GAM449 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6529] Nucleotide sequences of the GAM449 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM449 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM449 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM449 are further described hereinbelow with reference to Table Table1.

[6530] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM449 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6531]

[6532] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 450 (GAM450) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6533] GAM450 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM450 was detected is described hereinabove with reference to Figs. 2-8.

[6534] GAM450 gene, herein designated GAM GENE, and GAM450 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6535] GAM450 gene, herein designated GAM GENE, encodes a GAM450 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM450 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM450 precursor RNA is designated SEQ ID:7075, and is provided hereinbelow with reference to the sequence listing part.

[6536] GAM450 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM450 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6537] An enzyme complex designated DICER COMPLEX, dices the GAM450 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM450 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 25%) nucleotide sequence of GAM450 RNA is designated SEQ ID:7076, and is provided hereinbelow with reference to the sequence listing part.

[6538] GAM450 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM450 target RNA, herein designated GAM TARGET RNA.

GAM450 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6539] GAM450 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM450 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM450 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM450 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM450 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6540] The complementary binding of GAM450 RNA, herein designated GAM RNA, to target binding sites on GAM450 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM450 target RNA, herein designated GAM TARGET RNA, into GAM450 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6541] It is appreciated that GAM450 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM450 target genes. The mRNA of each one of this plurality of GAM450 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM450 RNA, herein designated GAM RNA, and which when bound by GAM450 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM450 target proteins.

[6542] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM450 gene, herein designated GAM GENE, on one or more GAM450 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6543] It is yet further appreciated that specific functions, and accordingly utilities, of GAM450 correlate with, and may be deduced from, the identity of the target genes which GAM450 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6544] Nucleotide sequences of the GAM450 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM450 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM450 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM450 are further described hereinbelow with reference to Table Table1.

[6545] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM450 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6546]

[6547] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 451 (GAM451) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6548] GAM451 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM451 was detected is described hereinabove with reference to Figs. 2-8.

[6549] GAM451 gene, herein designated GAM GENE, and GAM451 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6550] GAM451 gene, herein designated GAM GENE, encodes a

GAM451 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM451 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM451 precursor RNA is designated SEQ ID:7091, and is provided hereinbelow with reference to the sequence listing part.

[6551] GAM451 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM451 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6552] An enzyme complex designated DICER COMPLEX, dices the GAM451 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM451 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM451 RNA is designated SEQ ID:7092, and is provided hereinbelow with reference to the sequence listing part.

[6553] GAM451 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM451 target RNA, herein designated GAM TARGET RNA. GAM451 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6554] GAM451 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM451 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM451 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM451 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM451 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6555] The complementary binding of GAM451 RNA, herein designated GAM RNA, to target binding sites on GAM451 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM451 target RNA, herein designated GAM TARGET RNA, into GAM451 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6556] It is appreciated that GAM451 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM451 target genes. The mRNA of each one of this plurality of GAM451 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM451 RNA, herein designated GAM RNA, and which when bound by GAM451 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM451 target proteins.

[6557] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM451 gene, herein designated GAM GENE, on one or more GAM451 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6558] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM451 correlate with, and may be deduced from, the identity of the target genes which GAM451 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6559] Nucleotide sequences of the GAM451 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM451 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM451 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM451 are further described hereinbelow with reference to Table Table1.

[6560] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM451 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6561]

[6562] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 452 (GAM452) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[6563] GAM452 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM452 was detected is described hereinabove with reference to Figs. 2-8.

[6564] GAM452 gene, herein designated GAM GENE, and GAM452 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6565] GAM452 gene, herein designated GAM GENE, encodes a GAM452 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM452 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM452 precursor RNA is designated SEQ ID:7099, and is provided hereinbelow with reference to the sequence listing part.

[6566] GAM452 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM452 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6567] An enzyme complex designated DICER COMPLEX, dices the GAM452 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM452 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 24%) nucleotide sequence of GAM452 RNA is designated SEQ ID:7100, and is provided hereinbelow with reference to the sequence listing part.

[6568] GAM452 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM452 target RNA, herein designated GAM TARGET RNA. GAM452 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6569] GAM452 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM452 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM452 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM452 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM452 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6570] The complementary binding of GAM452 RNA, herein designated GAM RNA, to target binding sites on GAM452 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM452 target RNA, herein designated GAM TARGET RNA, into GAM452 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6571] It is appreciated that GAM452 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM452 target genes. The mRNA of each one of this plurality of GAM452 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM452 RNA, herein designated GAM RNA, and which when bound by GAM452 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM452 target proteins.

[6572] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM452 gene, herein designated GAM GENE, on one or more GAM452 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6573] It is yet further appreciated that specific functions, and accordingly utilities, of GAM452 correlate with, and may be deduced from, the identity of the target genes which GAM452 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6574] Nucleotide sequences of the GAM452 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM452 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM452 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM452 are further described hereinbelow with reference to Table Table1.

[6575] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM452 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6576]

[6577] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 453 (GAM453) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6578] GAM453 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM453 was detected is described hereinabove with reference to Figs. 2-8.

[6579] GAM453 gene, herein designated GAM GENE, and GAM453 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6580] GAM453 gene, herein designated GAM GENE, encodes a GAM453 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM453 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM453 precursor RNA is designated SEQ ID:7116, and is provided hereinbelow with reference to the sequence listing part.

[6581] GAM453 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM453 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6582] An enzyme complex designated DICER COMPLEX, dices the GAM453 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM453 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM453 RNA is designated SEQ ID:3102, and is provided

hereinbelow with reference to the sequence listing part.

[6583] GAM453 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM453 target RNA, herein designated GAM TARGET RNA.
GAM453 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6584] GAM453 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM453 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM453 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM453 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM453 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6585] The complementary binding of GAM453 RNA, herein designated GAM RNA, to target binding sites on GAM453 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM453 target RNA, herein designated GAM TARGET RNA, into GAM453 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6586] It is appreciated that GAM453 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM453 target genes. The mRNA of each one of this plurality of GAM453 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM453 RNA, herein designated GAM RNA, and which when bound by GAM453 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM453 tar-

get proteins.

[6587] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM453 gene, herein designated GAM GENE, on one or more GAM453 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6588] It is yet further appreciated that specific functions, and accordingly utilities, of GAM453 correlate with, and may be deduced from, the identity of the target genes which GAM453 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6589] Nucleotide sequences of the GAM453 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM453 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM453 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM453 are further described hereinbelow with reference to Table Table1.

[6590] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM453 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6591]

[6592] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 454 (GAM454) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6593] GAM454 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM454 was detected is described hereinabove with reference to Figs. 2-8.

[6594] GAM454 gene, herein designated GAM GENE, and GAM454 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6595] GAM454 gene, herein designated GAM GENE, encodes a GAM454 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM454 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM454 precursor RNA is designated SEQ ID:7127, and is provided hereinbelow with reference to the sequence listing part.

[6596] GAM454 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM454 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6597] An enzyme complex designated DICER COMPLEX, dices

the GAM454 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM454 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM454 RNA is designated SEQ ID:7128, and is provided hereinbelow with reference to the sequence listing part.

[6598] GAM454 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM454 target RNA, herein designated GAM TARGET RNA. GAM454 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6599] GAM454 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM454 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM454

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM454 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM454 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6600] The complementary binding of GAM454 RNA, herein designated GAM RNA, to target binding sites on GAM454 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM454 target RNA, herein designated GAM TARGET RNA, into GAM454 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6601] It is appreciated that GAM454 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM454 target genes. The mRNA of each one of this plurality of GAM454 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM454 RNA, herein designated GAM RNA, and which when bound by GAM454 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM454 target proteins.

[6602] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM454 gene, herein designated GAM GENE, on one or more GAM454 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6603] It is yet further appreciated that specific functions, and accordingly utilities, of GAM454 correlate with, and may be deduced from, the identity of the target genes which GAM454 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6604] Nucleotide sequences of the GAM454 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM454 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM454 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM454 are further described hereinbelow with reference to Table Table1.

[6605] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM454 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6606]

[6607] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 455 (GAM455) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6608] GAM455 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM455 was detected is described hereinabove with reference to Figs. 2-8.

[6609] GAM455 gene, herein designated GAM GENE, and GAM455 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6610] GAM455 gene, herein designated GAM GENE, encodes a GAM455 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM455 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM455 precursor RNA is designated SEQ ID:7145, and is provided hereinbelow with reference to the sequence listing part.

[6611] GAM455 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM455 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6612] An enzyme complex designated DICER COMPLEX, dices the GAM455 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM455 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM455 RNA is designated SEQ ID:7146, and is provided hereinbelow with reference to the sequence listing part.

[6613] GAM455 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM455 target RNA, herein designated GAM TARGET RNA. GAM455 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6614] GAM455 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM455 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM455 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM455 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM455 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[6615] The complementary binding of GAM455 RNA, herein designated GAM RNA, to target binding sites on GAM455 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM455 target RNA, herein designated GAM TARGET RNA, into GAM455 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6616] It is appreciated that GAM455 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM455 target genes. The mRNA of each one of this plurality of GAM455 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM455 RNA, herein designated GAM RNA, and which when bound by GAM455 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM455 target proteins.

[6617] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM455 gene, herein designated GAM GENE, on one or

more GAM455 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6618] It is yet further appreciated that specific functions, and accordingly utilities, of GAM455 correlate with, and may be deduced from, the identity of the target genes which GAM455 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6619] Nucleotide sequences of the GAM455 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM455 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM455 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM455 are further de-

scribed hereinbelow with reference to Table Table1.

[6620] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM455 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6621]

[6622] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 456 (GAM456) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6623] GAM456 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM456 was detected is described hereinabove with reference to Figs. 2-8.

[6624] GAM456 gene, herein designated GAM GENE, and GAM456 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6625] GAM456 gene, herein designated GAM GENE, encodes a GAM456 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM456 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM456 precursor RNA is designated SEQ ID:7191, and is provided hereinbelow with reference to the sequence listing part.

[6626] GAM456 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM456 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6627] An enzyme complex designated DICER COMPLEX, dices the GAM456 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM456 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM456 RNA is designated SEQ ID:7192, and is provided hereinbelow with reference to the sequence listing part.

[6628] GAM456 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM456 target RNA, herein designated GAM TARGET RNA. GAM456 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6629] GAM456 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM456 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM456 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM456 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM456 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6630] The complementary binding of GAM456 RNA, herein designated GAM RNA, to target binding sites on GAM456 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM456 target RNA, herein designated GAM TARGET RNA, into GAM456 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6631] It is appreciated that GAM456 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM456 target genes. The mRNA of each one of this plurality of GAM456 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM456 RNA, herein designated GAM RNA, and which when bound by GAM456 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM456 target proteins.

[6632] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM456 gene, herein designated GAM GENE, on one or more GAM456 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6633] It is yet further appreciated that specific functions, and accordingly utilities, of GAM456 correlate with, and may

be deduced from, the identity of the target genes which GAM456 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6634] Nucleotide sequences of the GAM456 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM456 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM456 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM456 are further described hereinbelow with reference to Table Table1.

[6635] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM456 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6636]

[6637] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 457 (GAM457) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6638] GAM457 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM457 was detected is described hereinabove with reference to Figs. 2-8.

[6639] GAM457 gene, herein designated GAM GENE, and GAM457 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6640] GAM457 gene, herein designated GAM GENE, encodes a GAM457 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM457 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM457 precursor RNA is designated SEQ ID:7205, and is provided hereinbelow with reference to the sequence listing part.

[6641] GAM457 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM457 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6642] An enzyme complex designated DICER COMPLEX, dices the GAM457 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM457 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 26%) nucleotide sequence of GAM457 RNA is designated SEQ ID:7206, and is provided hereinbelow with reference to the sequence listing part.

[6643] GAM457 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM457 target RNA, herein designated GAM TARGET RNA. GAM457 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6644] GAM457 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM457 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM457 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM457 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM457 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6645] The complementary binding of GAM457 RNA, herein designated GAM RNA, to target binding sites on GAM457 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM457 target RNA, herein designated GAM TARGET RNA, into GAM457 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6646] It is appreciated that GAM457 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM457 target genes. The mRNA of each one of this plurality of GAM457 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM457 RNA, herein designated GAM RNA, and which when bound by GAM457 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM457 target proteins.

[6647] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM457 gene, herein designated GAM GENE, on one or more GAM457 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6648] It is yet further appreciated that specific functions, and accordingly utilities, of GAM457 correlate with, and may be deduced from, the identity of the target genes which GAM457 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6649] Nucleotide sequences of the GAM457 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM457 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM457 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM457 are further described hereinbelow with reference to Table Table1.

[6650] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM457 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6651]

[6652] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 458 (GAM458) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6653] GAM458 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM458 was detected is described hereinabove with reference to Figs. 2-8.

[6654] GAM458 gene, herein designated GAM GENE, and GAM458 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6655] GAM458 gene, herein designated GAM GENE, encodes a GAM458 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM458 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM458 precursor RNA is desig-

nated SEQ ID:7226, and is provided hereinbelow with reference to the sequence listing part.

[6656] GAM458 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM458 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6657] An enzyme complex designated DICER COMPLEX, dices the GAM458 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM458 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM458 RNA is designated SEQ ID:7227, and is provided hereinbelow with reference to the sequence listing part.

[6658] GAM458 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM458 target RNA, herein designated GAM TARGET RNA. GAM458 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6659] GAM458 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM458 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM458 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM458 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM458

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6660] The complementary binding of GAM458 RNA, herein designated GAM RNA, to target binding sites on GAM458 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM458 target RNA, herein designated GAM TARGET RNA, into GAM458 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6661] It is appreciated that GAM458 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM458 target genes. The mRNA of each one of this plurality of GAM458 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM458 RNA, herein designated GAM RNA, and which when bound by GAM458 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM458 target proteins.

[6662] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM458 gene, herein designated GAM GENE, on one or more GAM458 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6663] It is yet further appreciated that specific functions, and accordingly utilities, of GAM458 correlate with, and may be deduced from, the identity of the target genes which GAM458 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6664] Nucleotide sequences of the GAM458 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM458 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM458 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM458 are further described hereinbelow with reference to Table Table1.

[6665] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM458 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6666]

[6667] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 459 (GAM459) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6668] GAM459 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM459 was detected is described hereinabove with reference to Figs. 2-8.

[6669] GAM459 gene, herein designated GAM GENE, and

GAM459 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6670] GAM459 gene, herein designated GAM GENE, encodes a GAM459 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM459 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM459 precursor RNA is designated SEQ ID:7262, and is provided hereinbelow with reference to the sequence listing part.

[6671] GAM459 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM459 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6672] An enzyme complex designated DICER COMPLEX, dices the GAM459 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM459 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM459 RNA is designated SEQ ID:7263, and is provided hereinbelow with reference to the sequence listing part.

[6673] GAM459 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM459 target RNA, herein designated GAM TARGET RNA. GAM459 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6674] GAM459 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM459 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM459 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM459 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM459 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6675] The complementary binding of GAM459 RNA, herein designated GAM RNA, to target binding sites on GAM459 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM459 target RNA, herein designated GAM TARGET RNA, into GAM459 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6676] It is appreciated that GAM459 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM459 target genes. The mRNA of each one of this plurality of GAM459 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM459 RNA, herein designated GAM RNA, and which when bound by GAM459 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM459 target proteins.

[6677] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM459 gene, herein designated GAM GENE, on one or more GAM459 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6678] It is yet further appreciated that specific functions, and accordingly utilities, of GAM459 correlate with, and may be deduced from, the identity of the target genes which GAM459 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6679] Nucleotide sequences of the GAM459 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM459 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM459 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM459 are further described hereinbelow with reference to Table Table1.

[6680] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM459 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6681]

[6682] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 460 (GAM460) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6683] GAM460 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM460 was detected is described hereinabove with reference to Figs. 2-8.

[6684] GAM460 gene, herein designated GAM GENE, and GAM460 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6685] GAM460 gene, herein designated GAM GENE, encodes a GAM460 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM460 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM460 precursor RNA is designated SEQ ID:7273, and is provided hereinbelow with reference to the sequence listing part.

[6686] GAM460 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM460 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6687] An enzyme complex designated DICER COMPLEX, dices the GAM460 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM460 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM460 RNA is designated SEQ ID:7274, and is provided hereinbelow with reference to the sequence listing part.

[6688] GAM460 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM460 target RNA, herein designated GAM TARGET RNA. GAM460 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6689] GAM460 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM460 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM460 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM460 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM460 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6690] The complementary binding of GAM460 RNA, herein designated GAM RNA, to target binding sites on GAM460 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM460 target RNA, herein designated GAM TARGET RNA, into GAM460 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6691] It is appreciated that GAM460 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM460 target genes. The mRNA of each one of this plurality of GAM460 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM460 RNA, herein designated GAM RNA, and which when bound by GAM460 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM460 target proteins.

[6692] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM460 gene, herein designated GAM GENE, on one or more GAM460 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6693] It is yet further appreciated that specific functions, and accordingly utilities, of GAM460 correlate with, and may be deduced from, the identity of the target genes which GAM460 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6694] Nucleotide sequences of the GAM460 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM460 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM460 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM460 are further described hereinbelow with reference to Table Table1.

[6695] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM460 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6696]

[6697] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 461 (GAM461) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6698] GAM461 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM461 was detected is described hereinabove with reference to Figs. 2-8.

[6699] GAM461 gene, herein designated GAM GENE, and GAM461 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6700] GAM461 gene, herein designated GAM GENE, encodes a GAM461 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM461 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM461 precursor RNA is designated SEQ ID:7296, and is provided hereinbelow with reference to the sequence listing part.

[6701] GAM461 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM461 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6702] An enzyme complex designated DICER COMPLEX, dices the GAM461 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM461 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM461 RNA is designated SEQ ID:5801, and is provided hereinbelow with reference to the sequence listing part.

[6703] GAM461 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM461 target RNA, herein designated GAM TARGET RNA. GAM461 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6704] GAM461 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM461 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM461 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM461 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM461 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6705] The complementary binding of GAM461 RNA, herein designated GAM RNA, to target binding sites on GAM461 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM461 target RNA, herein designated GAM TARGET RNA, into GAM461 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6706] It is appreciated that GAM461 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM461 target genes. The mRNA of each one of this plurality of GAM461 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM461 RNA,

herein designated GAM RNA, and which when bound by GAM461 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM461 target proteins.

[6707] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM461 gene, herein designated GAM GENE, on one or more GAM461 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6708] It is yet further appreciated that specific functions, and accordingly utilities, of GAM461 correlate with, and may be deduced from, the identity of the target genes which

GAM461 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6709] Nucleotide sequences of the GAM461 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM461 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM461 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM461 are further described hereinbelow with reference to Table Table1.

[6710] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM461 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6711]

[6712] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 462 (GAM462) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6713] GAM462 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM462 was detected is described hereinabove with reference to Figs. 2-8.

[6714] GAM462 gene, herein designated GAM GENE, and GAM462 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6715] GAM462 gene, herein designated GAM GENE, encodes a GAM462 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM462 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM462 precursor RNA is designated SEQ ID:7301, and is provided hereinbelow with reference to the sequence listing part.

[6716] GAM462 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM462 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[6717] An enzyme complex designated DICER COMPLEX, dices the GAM462 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM462 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM462 RNA is designated SEQ ID:7302, and is provided hereinbelow with reference to the sequence listing part.

[6718] GAM462 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM462 target RNA, herein designated GAM TARGET RNA.
GAM462 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6719] GAM462 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM462 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM462 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM462 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM462 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6720] The complementary binding of GAM462 RNA, herein designated GAM RNA, to target binding sites on GAM462 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM462 target RNA, herein desig-

nated GAM TARGET RNA, into GAM462 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6721] It is appreciated that GAM462 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM462 target genes. The mRNA of each one of this plurality of GAM462 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM462 RNA, herein designated GAM RNA, and which when bound by GAM462 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM462 target proteins.

[6722] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM462 gene, herein designated GAM GENE, on one or more GAM462 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6723] It is yet further appreciated that specific functions, and accordingly utilities, of GAM462 correlate with, and may be deduced from, the identity of the target genes which GAM462 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6724] Nucleotide sequences of the GAM462 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM462 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM462 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM462 are further described hereinbelow with reference to Table Table1.

[6725] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM462 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[6726]

[6727] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 463 (GAM463) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6728] GAM463 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM463 was detected is described hereinabove with reference to Figs. 2-8.

[6729] GAM463 gene, herein designated GAM GENE, and GAM463 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6730] GAM463 gene, herein designated GAM GENE, encodes a GAM463 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM463 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM463 precursor RNA is designated SEQ ID:7309, and is provided hereinbelow with ref-

erence to the sequence listing part.

[6731] GAM463 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM463 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6732] An enzyme complex designated DICER COMPLEX, dices the GAM463 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM463 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM463 RNA is designated SEQ ID:7310, and is provided hereinbelow with reference to the sequence listing part.

[6733] GAM463 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM463 target RNA, herein designated GAM TARGET RNA.

GAM463 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6734] GAM463 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM463 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM463 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM463 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM463 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6735] The complementary binding of GAM463 RNA, herein designated GAM RNA, to target binding sites on GAM463 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM463 target RNA, herein designated GAM TARGET RNA, into GAM463 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6736] It is appreciated that GAM463 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM463 target genes. The mRNA of each one of this plurality of GAM463 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM463 RNA, herein designated GAM RNA, and which when bound by GAM463 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM463 target proteins.

[6737] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM463 gene, herein designated GAM GENE, on one or more GAM463 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6738] It is yet further appreciated that specific functions, and accordingly utilities, of GAM463 correlate with, and may be deduced from, the identity of the target genes which GAM463 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6739] Nucleotide sequences of the GAM463 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM463 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM463 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM463 are further described hereinbelow with reference to Table Table1.

[6740] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM463 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6741]

[6742] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 464 (GAM464) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6743] GAM464 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM464 was detected is described hereinabove with reference to Figs. 2-8.

[6744] GAM464 gene, herein designated GAM GENE, and GAM464 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[6745] GAM464 gene, herein designated GAM GENE, encodes a GAM464 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM464 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM464 precursor RNA is designated SEQ ID:7323, and is provided hereinbelow with reference to the sequence listing part.

[6746] GAM464 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM464 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6747] An enzyme complex designated DICER COMPLEX, dices the GAM464 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM464 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM464 RNA is designated SEQ ID:7324, and is provided hereinbelow with reference to the sequence listing part.

[6748] GAM464 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM464 target RNA, herein designated GAM TARGET RNA. GAM464 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6749] GAM464 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM464 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM464 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM464 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM464 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6750] The complementary binding of GAM464 RNA, herein designated GAM RNA, to target binding sites on GAM464 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM464 target RNA, herein designated GAM TARGET RNA, into GAM464 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6751] It is appreciated that GAM464 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM464 target genes. The mRNA of each one of this plurality of GAM464 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM464 RNA, herein designated GAM RNA, and which when bound by GAM464 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM464 target proteins.

[6752] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM464 gene, herein designated GAM GENE, on one or more GAM464 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[6753] It is yet further appreciated that specific functions, and accordingly utilities, of GAM464 correlate with, and may be deduced from, the identity of the target genes which GAM464 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6754] Nucleotide sequences of the GAM464 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM464 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM464 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM464 are further described hereinbelow with reference to Table Table1.

[6755] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM464 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6756]

[6757] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

465 (GAM465) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6758] GAM465 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM465 was detected is described hereinabove with reference to Figs. 2-8.

[6759] GAM465 gene, herein designated GAM GENE, and GAM465 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6760] GAM465 gene, herein designated GAM GENE, encodes a GAM465 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM465 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM465 precursor RNA is designated SEQ ID:7338, and is provided hereinbelow with reference to the sequence listing part.

[6761] GAM465 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM465 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6762] An enzyme complex designated DICER COMPLEX, dices the GAM465 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM465 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 35%) nucleotide sequence of GAM465 RNA is designated SEQ ID:7339, and is provided hereinbelow with reference to the sequence listing part.

[6763] GAM465 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM465 target RNA, herein designated GAM TARGET RNA. GAM465 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6764] GAM465 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM465 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM465 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM465 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM465 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6765] The complementary binding of GAM465 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM465 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM465 target RNA, herein designated GAM TARGET RNA, into GAM465 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6766] It is appreciated that GAM465 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM465 target genes. The mRNA of each one of this plurality of GAM465 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM465 RNA, herein designated GAM RNA, and which when bound by GAM465 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM465 target proteins.

[6767] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM465 gene, herein designated GAM GENE, on one or more GAM465 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6768] It is yet further appreciated that specific functions, and accordingly utilities, of GAM465 correlate with, and may be deduced from, the identity of the target genes which GAM465 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6769] Nucleotide sequences of the GAM465 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM465 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM465 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM465 are further described hereinbelow with reference to Table Table1.

[6770] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM465 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6771]

[6772] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 466 (GAM466) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6773] GAM466 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM466 was detected is described hereinabove with reference to Figs. 2-8.

[6774] GAM466 gene, herein designated GAM GENE, and GAM466 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6775] GAM466 gene, herein designated GAM GENE, encodes a GAM466 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM466 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM466 precursor RNA is designated SEQ ID:7348, and is provided hereinbelow with reference to the sequence listing part.

[6776] GAM466 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM466 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6777] An enzyme complex designated DICER COMPLEX, dices the GAM466 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM466 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 40%) nucleotide sequence of GAM466 RNA is designated SEQ ID:7349, and is provided hereinbelow with reference to the sequence listing part.

[6778] GAM466 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM466 target RNA, herein designated GAM TARGET RNA. GAM466 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6779] GAM466 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM466 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM466 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM466 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM466 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6780] The complementary binding of GAM466 RNA, herein designated GAM RNA, to target binding sites on GAM466 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM466 target RNA, herein designated GAM TARGET RNA, into GAM466 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6781] It is appreciated that GAM466 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM466 target genes. The mRNA of each one of this plurality of GAM466 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM466 RNA, herein designated GAM RNA, and which when bound by

GAM466 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM466 target proteins.

[6782] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM466 gene, herein designated GAM GENE, on one or more GAM466 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6783] It is yet further appreciated that specific functions, and accordingly utilities, of GAM466 correlate with, and may be deduced from, the identity of the target genes which GAM466 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[6784] Nucleotide sequences of the GAM466 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM466 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM466 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM466 are further described hereinbelow with reference to Table Table1.

[6785] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM466 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6786]

[6787] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 467 (GAM467) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6788] GAM467 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM467 was detected is described hereinabove with reference to Figs. 2-8.

[6789] GAM467 gene, herein designated GAM GENE, and GAM467 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6790] GAM467 gene, herein designated GAM GENE, encodes a GAM467 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM467 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM467 precursor RNA is designated SEQ ID:7361, and is provided hereinbelow with reference to the sequence listing part.

[6791] GAM467 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM467 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[6792] An enzyme complex designated DICER COMPLEX, dices the GAM467 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM467 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM467 RNA is designated SEQ ID:7362, and is provided hereinbelow with reference to the sequence listing part.

[6793] GAM467 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM467 target RNA, herein designated GAM TARGET RNA. GAM467 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6794] GAM467 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM467 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM467 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM467 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM467 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6795] The complementary binding of GAM467 RNA, herein designated GAM RNA, to target binding sites on GAM467 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM467 target RNA, herein designated GAM TARGET RNA, into GAM467 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6796] It is appreciated that GAM467 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM467 target genes. The mRNA of each one of this plurality of GAM467 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM467 RNA, herein designated GAM RNA, and which when bound by GAM467 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM467 target proteins.

[6797] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM467 gene, herein designated GAM GENE, on one or more GAM467 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6798] It is yet further appreciated that specific functions, and accordingly utilities, of GAM467 correlate with, and may be deduced from, the identity of the target genes which GAM467 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6799] Nucleotide sequences of the GAM467 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM467 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM467 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM467 are further described hereinbelow with reference to Table Table1.

[6800] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM467 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6801]

[6802] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 468 (GAM468) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6803] GAM468 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM468 was detected is described hereinabove with reference to Figs. 2-8.

[6804] GAM468 gene, herein designated GAM GENE, and GAM468 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6805] GAM468 gene, herein designated GAM GENE, encodes a GAM468 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM468 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM468 precursor RNA is designated SEQ ID:7380, and is provided hereinbelow with reference to the sequence listing part.

[6806] GAM468 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM468 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6807] An enzyme complex designated DICER COMPLEX, dices the GAM468 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM468 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM468 RNA is designated SEQ ID:7381, and is provided hereinbelow with reference to the sequence listing part.

[6808] GAM468 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM468

target RNA, herein designated GAM TARGET RNA.

GAM468 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6809] GAM468 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM468 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM468 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM468 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM468 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6810] The complementary binding of GAM468 RNA, herein designated GAM RNA, to target binding sites on GAM468 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM468 target RNA, herein designated GAM TARGET RNA, into GAM468 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6811] It is appreciated that GAM468 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM468 target genes. The mRNA of each one of this plurality of GAM468 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM468 RNA, herein designated GAM RNA, and which when bound by GAM468 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM468 target proteins.

[6812] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM468 gene, herein designated GAM GENE, on one or more GAM468 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6813] It is yet further appreciated that specific functions, and accordingly utilities, of GAM468 correlate with, and may be deduced from, the identity of the target genes which GAM468 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6814] Nucleotide sequences of the GAM468 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM468 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM468 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM468 are further described hereinbelow with reference to Table Table1.

[6815] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM468 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6816]

[6817] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 469 (GAM469) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6818] GAM469 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM469 was detected is described hereinabove with reference to Figs. 2-8.

[6819] GAM469 gene, herein designated GAM GENE, and GAM469 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6820] GAM469 gene, herein designated GAM GENE, encodes a GAM469 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM469 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM469 precursor RNA is designated SEQ ID:7395, and is provided hereinbelow with reference to the sequence listing part.

[6821] GAM469 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM469 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6822] An enzyme complex designated DICER COMPLEX, dices the GAM469 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM469 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 69%) nucleotide sequence of GAM469 RNA is designated SEQ ID:7396, and is provided hereinbelow with reference to the sequence listing part.

[6823] GAM469 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM469 target RNA, herein designated GAM TARGET RNA. GAM469 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6824] GAM469 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM469 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM469 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM469 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM469 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6825] The complementary binding of GAM469 RNA, herein designated GAM RNA, to target binding sites on GAM469 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM469 target RNA, herein designated GAM TARGET RNA, into GAM469 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6826] It is appreciated that GAM469 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM469 target genes. The mRNA of each one of this plu-

rality of GAM469 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM469 RNA, herein designated GAM RNA, and which when bound by GAM469 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM469 target proteins.

[6827] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM469 gene, herein designated GAM GENE, on one or more GAM469 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6828] It is yet further appreciated that specific functions, and accordingly utilities, of GAM469 correlate with, and may be deduced from, the identity of the target genes which GAM469 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6829] Nucleotide sequences of the GAM469 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM469 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM469 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM469 are further described hereinbelow with reference to Table Table1.

[6830] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM469 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6831]

[6832] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 470 (GAM470) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[6833] GAM470 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM470 was detected is described hereinabove with reference to Figs. 2-8.

[6834] GAM470 gene, herein designated GAM GENE, and GAM470 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6835] GAM470 gene, herein designated GAM GENE, encodes a GAM470 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM470 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM470 precursor RNA is designated SEQ ID:7429, and is provided hereinbelow with reference to the sequence listing part.

[6836] GAM470 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM470 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6837] An enzyme complex designated DICER COMPLEX, dices the GAM470 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM470 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 39%) nucleotide sequence of GAM470 RNA is designated SEQ ID:7430, and is provided hereinbelow with reference to the sequence listing part.

[6838] GAM470 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM470 target RNA, herein designated GAM TARGET RNA.
GAM470 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[6839] GAM470 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM470 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM470 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM470 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM470 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6840] The complementary binding of GAM470 RNA, herein designated GAM RNA, to target binding sites on GAM470 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM470 target RNA, herein designated GAM TARGET RNA, into GAM470 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6841] It is appreciated that GAM470 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM470 target genes. The mRNA of each one of this plurality of GAM470 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM470 RNA, herein designated GAM RNA, and which when bound by GAM470 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM470 target proteins.

[6842] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM470 gene, herein designated GAM GENE, on one or more GAM470 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6843] It is yet further appreciated that specific functions, and accordingly utilities, of GAM470 correlate with, and may be deduced from, the identity of the target genes which GAM470 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6844] Nucleotide sequences of the GAM470 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM470 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM470 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM470 are further described hereinbelow with reference to Table Table1.

[6845] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM470 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6846]

[6847] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 471 (GAM471) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6848] GAM471 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM471 was detected is described hereinabove with reference to Figs. 2-8.

[6849] GAM471 gene, herein designated GAM GENE, and GAM471 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6850] GAM471 gene, herein designated GAM GENE, encodes a GAM471 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM471 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM471 precursor RNA is designated SEQ ID:7457, and is provided hereinbelow with reference to the sequence listing part.

[6851] GAM471 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM471 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6852] An enzyme complex designated DICER COMPLEX, dices the GAM471 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM471 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 33%) nucleotide sequence of

GAM471 RNA is designated SEQ ID:7458, and is provided hereinbelow with reference to the sequence listing part.

[6853] GAM471 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM471 target RNA, herein designated GAM TARGET RNA. GAM471 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6854] GAM471 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM471 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM471 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM471 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM471 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6855] The complementary binding of GAM471 RNA, herein designated GAM RNA, to target binding sites on GAM471 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM471 target RNA, herein designated GAM TARGET RNA, into GAM471 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6856] It is appreciated that GAM471 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM471 target genes. The mRNA of each one of this plurality of GAM471 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM471 RNA, herein designated GAM RNA, and which when bound by GAM471 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM471 target proteins.

[6857] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM471 gene, herein designated GAM GENE, on one or more GAM471 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6858] It is yet further appreciated that specific functions, and accordingly utilities, of GAM471 correlate with, and may be deduced from, the identity of the target genes which GAM471 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6859] Nucleotide sequences of the GAM471 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM471 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM471 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM471 are further described hereinbelow with reference to Table Table1.

[6860] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM471 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6861]

[6862] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 472 (GAM472) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6863] GAM472 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM472 was detected is described hereinabove

with reference to Figs. 2-8.

[6864] GAM472 gene, herein designated GAM GENE, and GAM472 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6865] GAM472 gene, herein designated GAM GENE, encodes a GAM472 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM472 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM472 precursor RNA is designated SEQ ID:7463, and is provided hereinbelow with reference to the sequence listing part.

[6866] GAM472 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM472 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6867] An enzyme complex designated DICER COMPLEX, dices the GAM472 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM472 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM472 RNA is designated SEQ ID:7464, and is provided hereinbelow with reference to the sequence listing part.

[6868] GAM472 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM472 target RNA, herein designated GAM TARGET RNA. GAM472 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6869] GAM472 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM472 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM472 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM472 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM472 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6870] The complementary binding of GAM472 RNA, herein designated GAM RNA, to target binding sites on GAM472 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM472 target RNA, herein designated GAM TARGET RNA, into GAM472 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[6871] It is appreciated that GAM472 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM472 target genes. The mRNA of each one of this plurality of GAM472 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM472 RNA, herein designated GAM RNA, and which when bound by GAM472 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM472 target proteins.

[6872] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM472 gene, herein designated GAM GENE, on one or more GAM472 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6873] It is yet further appreciated that specific functions, and accordingly utilities, of GAM472 correlate with, and may be deduced from, the identity of the target genes which GAM472 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6874] Nucleotide sequences of the GAM472 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM472 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM472 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM472 are further described hereinbelow with reference to Table Table1.

[6875] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM472 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6876]

[6877] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 473 (GAM473) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6878] GAM473 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM473 was detected is described hereinabove with reference to Figs. 2-8.

[6879] GAM473 gene, herein designated GAM GENE, and GAM473 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6880] GAM473 gene, herein designated GAM GENE, encodes a GAM473 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM473 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM473 precursor RNA is designated SEQ ID:7481, and is provided hereinbelow with reference to the sequence listing part.

[6881] GAM473 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM473 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6882] An enzyme complex designated DICER COMPLEX, dices the GAM473 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM473 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 18%) nucleotide sequence of GAM473 RNA is designated SEQ ID:7482, and is provided hereinbelow with reference to the sequence listing part.

[6883] GAM473 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM473 target RNA, herein designated GAM TARGET RNA.

GAM473 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6884] GAM473 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM473 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM473 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM473 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM473 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6885] The complementary binding of GAM473 RNA, herein designated GAM RNA, to target binding sites on GAM473 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM473 target RNA, herein designated GAM TARGET RNA, into GAM473 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6886] It is appreciated that GAM473 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM473 target genes. The mRNA of each one of this plurality of GAM473 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM473 RNA, herein designated GAM RNA, and which when bound by GAM473 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM473 target proteins.

[6887] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM473 gene, herein designated GAM GENE, on one or more GAM473 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6888] It is yet further appreciated that specific functions, and accordingly utilities, of GAM473 correlate with, and may be deduced from, the identity of the target genes which GAM473 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6889] Nucleotide sequences of the GAM473 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM473 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM473 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM473 are further described hereinbelow with reference to Table Table1.

[6890] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM473 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6891]

[6892] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 474 (GAM474) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6893] GAM474 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM474 was detected is described hereinabove with reference to Figs. 2-8.

[6894] GAM474 gene, herein designated GAM GENE, and GAM474 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6895] GAM474 gene, herein designated GAM GENE, encodes a

GAM474 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM474 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM474 precursor RNA is designated SEQ ID:7493, and is provided hereinbelow with reference to the sequence listing part.

[6896] GAM474 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM474 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6897] An enzyme complex designated DICER COMPLEX, dices the GAM474 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM474 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 43%) nucleotide sequence of GAM474 RNA is designated SEQ ID:7494, and is provided hereinbelow with reference to the sequence listing part.

[6898] GAM474 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM474 target RNA, herein designated GAM TARGET RNA. GAM474 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6899] GAM474 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM474 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM474 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM474 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM474 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6900] The complementary binding of GAM474 RNA, herein designated GAM RNA, to target binding sites on GAM474 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM474 target RNA, herein designated GAM TARGET RNA, into GAM474 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6901] It is appreciated that GAM474 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM474 target genes. The mRNA of each one of this plurality of GAM474 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM474 RNA, herein designated GAM RNA, and which when bound by GAM474 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM474 target proteins.

[6902] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM474 gene, herein designated GAM GENE, on one or more GAM474 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6903] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM474 correlate with, and may be deduced from, the identity of the target genes which GAM474 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6904] Nucleotide sequences of the GAM474 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM474 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM474 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM474 are further described hereinbelow with reference to Table Table1.

[6905] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM474 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6906]

[6907] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 475 (GAM475) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[6908] GAM475 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM475 was detected is described hereinabove with reference to Figs. 2-8.

[6909] GAM475 gene, herein designated GAM GENE, and GAM475 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6910] GAM475 gene, herein designated GAM GENE, encodes a GAM475 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM475 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM475 precursor RNA is designated SEQ ID:7511, and is provided hereinbelow with reference to the sequence listing part.

[6911] GAM475 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM475 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6912] An enzyme complex designated DICER COMPLEX, dices the GAM475 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM475 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 27%) nucleotide sequence of GAM475 RNA is designated SEQ ID:7512, and is provided hereinbelow with reference to the sequence listing part.

[6913] GAM475 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM475 target RNA, herein designated GAM TARGET RNA. GAM475 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6914] GAM475 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM475 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM475 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM475 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM475 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6915] The complementary binding of GAM475 RNA, herein designated GAM RNA, to target binding sites on GAM475 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM475 target RNA, herein designated GAM TARGET RNA, into GAM475 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6916] It is appreciated that GAM475 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM475 target genes. The mRNA of each one of this plurality of GAM475 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM475 RNA, herein designated GAM RNA, and which when bound by GAM475 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM475 target proteins.

[6917] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM475 gene, herein designated GAM GENE, on one or more GAM475 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6918] It is yet further appreciated that specific functions, and accordingly utilities, of GAM475 correlate with, and may be deduced from, the identity of the target genes which GAM475 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6919] Nucleotide sequences of the GAM475 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM475 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM475 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM475 are further described hereinbelow with reference to Table Table1.

[6920] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM475 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6921]

[6922] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 476 (GAM476) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6923] GAM476 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM476 was detected is described hereinabove with reference to Figs. 2-8.

[6924] GAM476 gene, herein designated GAM GENE, and GAM476 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6925] GAM476 gene, herein designated GAM GENE, encodes a GAM476 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM476 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM476 precursor RNA is designated SEQ ID:7541, and is provided hereinbelow with reference to the sequence listing part.

[6926] GAM476 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM476 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6927] An enzyme complex designated DICER COMPLEX, dices the GAM476 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM476 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 55%) nucleotide sequence of GAM476 RNA is designated SEQ ID:7542, and is provided

hereinbelow with reference to the sequence listing part.

[6928] GAM476 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM476 target RNA, herein designated GAM TARGET RNA.

GAM476 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6929] GAM476 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM476 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM476 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM476 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM476 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6930] The complementary binding of GAM476 RNA, herein designated GAM RNA, to target binding sites on GAM476 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM476 target RNA, herein designated GAM TARGET RNA, into GAM476 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6931] It is appreciated that GAM476 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM476 target genes. The mRNA of each one of this plurality of GAM476 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM476 RNA, herein designated GAM RNA, and which when bound by GAM476 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM476 tar-

get proteins.

[6932] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM476 gene, herein designated GAM GENE, on one or more GAM476 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6933] It is yet further appreciated that specific functions, and accordingly utilities, of GAM476 correlate with, and may be deduced from, the identity of the target genes which GAM476 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6934] Nucleotide sequences of the GAM476 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM476 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM476 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM476 are further described hereinbelow with reference to Table Table1.

[6935] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM476 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6936]

[6937] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 477 (GAM477) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6938] GAM477 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM477 was detected is described hereinabove with reference to Figs. 2-8.

[6939] GAM477 gene, herein designated GAM GENE, and GAM477 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6940] GAM477 gene, herein designated GAM GENE, encodes a GAM477 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM477 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM477 precursor RNA is designated SEQ ID:7561, and is provided hereinbelow with reference to the sequence listing part.

[6941] GAM477 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM477 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6942] An enzyme complex designated DICER COMPLEX, dices

the GAM477 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM477 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM477 RNA is designated SEQ ID:7562, and is provided hereinbelow with reference to the sequence listing part.

[6943] GAM477 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM477 target RNA, herein designated GAM TARGET RNA. GAM477 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6944] GAM477 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM477 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM477

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM477 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM477 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6945] The complementary binding of GAM477 RNA, herein designated GAM RNA, to target binding sites on GAM477 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM477 target RNA, herein designated GAM TARGET RNA, into GAM477 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6946] It is appreciated that GAM477 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM477 target genes. The mRNA of each one of this plurality of GAM477 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM477 RNA, herein designated GAM RNA, and which when bound by GAM477 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM477 target proteins.

[6947] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM477 gene, herein designated GAM GENE, on one or more GAM477 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6948] It is yet further appreciated that specific functions, and accordingly utilities, of GAM477 correlate with, and may be deduced from, the identity of the target genes which GAM477 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6949] Nucleotide sequences of the GAM477 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM477 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM477 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM477 are further described hereinbelow with reference to Table Table1.

[6950] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM477 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6951]

[6952] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 478 (GAM478) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6953] GAM478 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM478 was detected is described hereinabove with reference to Figs. 2-8.

[6954] GAM478 gene, herein designated GAM GENE, and GAM478 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6955] GAM478 gene, herein designated GAM GENE, encodes a GAM478 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM478 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM478 precursor RNA is designated SEQ ID:7578, and is provided hereinbelow with reference to the sequence listing part.

[6956] GAM478 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM478 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6957] An enzyme complex designated DICER COMPLEX, dices the GAM478 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM478 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM478 RNA is designated SEQ ID:7579, and is provided hereinbelow with reference to the sequence listing part.

[6958] GAM478 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM478 target RNA, herein designated GAM TARGET RNA. GAM478 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6959] GAM478 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM478 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM478 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM478 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM478 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[6960] The complementary binding of GAM478 RNA, herein designated GAM RNA, to target binding sites on GAM478 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM478 target RNA, herein designated GAM TARGET RNA, into GAM478 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6961] It is appreciated that GAM478 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM478 target genes. The mRNA of each one of this plurality of GAM478 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM478 RNA, herein designated GAM RNA, and which when bound by GAM478 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM478 target proteins.

[6962] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM478 gene, herein designated GAM GENE, on one or

more GAM478 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6963] It is yet further appreciated that specific functions, and accordingly utilities, of GAM478 correlate with, and may be deduced from, the identity of the target genes which GAM478 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6964] Nucleotide sequences of the GAM478 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM478 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM478 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM478 are further de-

scribed hereinbelow with reference to Table Table1.

[6965] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM478 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6966]

[6967] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 479 (GAM479) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6968] GAM479 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM479 was detected is described hereinabove with reference to Figs. 2-8.

[6969] GAM479 gene, herein designated GAM GENE, and GAM479 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6970] GAM479 gene, herein designated GAM GENE, encodes a GAM479 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM479 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM479 precursor RNA is designated SEQ ID:7602, and is provided hereinbelow with reference to the sequence listing part.

[6971] GAM479 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM479 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6972] An enzyme complex designated DICER COMPLEX, dices the GAM479 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM479 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM479 RNA is designated SEQ ID:7603, and is provided hereinbelow with reference to the sequence listing part.

[6973] GAM479 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM479 target RNA, herein designated GAM TARGET RNA. GAM479 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6974] GAM479 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM479 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM479 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM479 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM479 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6975] The complementary binding of GAM479 RNA, herein designated GAM RNA, to target binding sites on GAM479 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM479 target RNA, herein designated GAM TARGET RNA, into GAM479 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6976] It is appreciated that GAM479 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM479 target genes. The mRNA of each one of this plurality of GAM479 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM479 RNA, herein designated GAM RNA, and which when bound by GAM479 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM479 target proteins.

[6977] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM479 gene, herein designated GAM GENE, on one or more GAM479 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6978] It is yet further appreciated that specific functions, and accordingly utilities, of GAM479 correlate with, and may

be deduced from, the identity of the target genes which GAM479 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6979] Nucleotide sequences of the GAM479 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM479 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM479 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM479 are further described hereinbelow with reference to Table Table1.

[6980] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM479 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6981]

[6982] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 480 (GAM480) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6983] GAM480 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM480 was detected is described hereinabove with reference to Figs. 2-8.

[6984] GAM480 gene, herein designated GAM GENE, and GAM480 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[6985] GAM480 gene, herein designated GAM GENE, encodes a GAM480 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM480 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM480 precursor RNA is designated SEQ ID:7622, and is provided hereinbelow with reference to the sequence listing part.

[6986] GAM480 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM480 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[6987] An enzyme complex designated DICER COMPLEX, dices the GAM480 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM480 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 51%) nucleotide sequence of GAM480 RNA is designated SEQ ID:7623, and is provided hereinbelow with reference to the sequence listing part.

[6988] GAM480 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM480 target RNA, herein designated GAM TARGET RNA. GAM480 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[6989] GAM480 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM480 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM480 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM480 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM480 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[6990] The complementary binding of GAM480 RNA, herein designated GAM RNA, to target binding sites on GAM480 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM480 target RNA, herein designated GAM TARGET RNA, into GAM480 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[6991] It is appreciated that GAM480 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM480 target genes. The mRNA of each one of this plurality of GAM480 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM480 RNA, herein designated GAM RNA, and which when bound by GAM480 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM480 target proteins.

[6992] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM480 gene, herein designated GAM GENE, on one or more GAM480 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[6993] It is yet further appreciated that specific functions, and accordingly utilities, of GAM480 correlate with, and may be deduced from, the identity of the target genes which GAM480 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[6994] Nucleotide sequences of the GAM480 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM480 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM480 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM480 are further described hereinbelow with reference to Table Table1.

[6995] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM480 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[6996]

[6997] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 481 (GAM481) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[6998] GAM481 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM481 was detected is described hereinabove with reference to Figs. 2-8.

[6999] GAM481 gene, herein designated GAM GENE, and GAM481 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7000] GAM481 gene, herein designated GAM GENE, encodes a GAM481 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM481 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM481 precursor RNA is desig-

nated SEQ ID:7628, and is provided hereinbelow with reference to the sequence listing part.

[7001] GAM481 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM481 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7002] An enzyme complex designated DICER COMPLEX, dices the GAM481 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM481 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM481 RNA is designated SEQ ID:7629, and is provided hereinbelow with reference to the sequence listing part.

[7003] GAM481 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM481 target RNA, herein designated GAM TARGET RNA. GAM481 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7004] GAM481 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM481 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM481 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM481 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM481

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7005] The complementary binding of GAM481 RNA, herein designated GAM RNA, to target binding sites on GAM481 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM481 target RNA, herein designated GAM TARGET RNA, into GAM481 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7006] It is appreciated that GAM481 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM481 target genes. The mRNA of each one of this plurality of GAM481 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM481 RNA, herein designated GAM RNA, and which when bound by GAM481 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM481 target proteins.

[7007] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM481 gene, herein designated GAM GENE, on one or more GAM481 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7008] It is yet further appreciated that specific functions, and accordingly utilities, of GAM481 correlate with, and may be deduced from, the identity of the target genes which GAM481 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7009] Nucleotide sequences of the GAM481 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM481 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM481 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM481 are further described hereinbelow with reference to Table Table1.

[7010] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM481 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7011]

[7012] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 482 (GAM482) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7013] GAM482 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM482 was detected is described hereinabove with reference to Figs. 2-8.

[7014] GAM482 gene, herein designated GAM GENE, and

GAM482 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7015] GAM482 gene, herein designated GAM GENE, encodes a GAM482 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM482 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM482 precursor RNA is designated SEQ ID:7634, and is provided hereinbelow with reference to the sequence listing part.

[7016] GAM482 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM482 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7017] An enzyme complex designated DICER COMPLEX, dices the GAM482 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM482 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM482 RNA is designated SEQ ID:7635, and is provided hereinbelow with reference to the sequence listing part.

[7018] GAM482 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM482 target RNA, herein designated GAM TARGET RNA. GAM482 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7019] GAM482 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM482 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM482 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM482 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM482 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7020] The complementary binding of GAM482 RNA, herein designated GAM RNA, to target binding sites on GAM482 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM482 target RNA, herein designated GAM TARGET RNA, into GAM482 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7021] It is appreciated that GAM482 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM482 target genes. The mRNA of each one of this plurality of GAM482 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM482 RNA, herein designated GAM RNA, and which when bound by GAM482 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM482 target proteins.

[7022] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM482 gene, herein designated GAM GENE, on one or more GAM482 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7023] It is yet further appreciated that specific functions, and accordingly utilities, of GAM482 correlate with, and may be deduced from, the identity of the target genes which GAM482 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7024] Nucleotide sequences of the GAM482 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM482 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM482 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM482 are further described hereinbelow with reference to Table Table1.

[7025] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM482 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7026]

[7027] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 483 (GAM483) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7028] GAM483 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM483 was detected is described hereinabove with reference to Figs. 2-8.

[7029] GAM483 gene, herein designated GAM GENE, and GAM483 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7030] GAM483 gene, herein designated GAM GENE, encodes a GAM483 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM483 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM483 precursor RNA is designated SEQ ID:7637, and is provided hereinbelow with reference to the sequence listing part.

[7031] GAM483 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM483 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7032] An enzyme complex designated DICER COMPLEX, dices the GAM483 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM483 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM483 RNA is designated SEQ ID:7638, and is provided hereinbelow with reference to the sequence listing part.

[7033] GAM483 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM483 target RNA, herein designated GAM TARGET RNA. GAM483 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7034] GAM483 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM483 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM483 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM483 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM483 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7035] The complementary binding of GAM483 RNA, herein designated GAM RNA, to target binding sites on GAM483 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM483 target RNA, herein designated GAM TARGET RNA, into GAM483 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7036] It is appreciated that GAM483 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM483 target genes. The mRNA of each one of this plurality of GAM483 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM483 RNA, herein designated GAM RNA, and which when bound by GAM483 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM483 target proteins.

[7037] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM483 gene, herein designated GAM GENE, on one or more GAM483 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7038] It is yet further appreciated that specific functions, and accordingly utilities, of GAM483 correlate with, and may be deduced from, the identity of the target genes which GAM483 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7039] Nucleotide sequences of the GAM483 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM483 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM483 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM483 are further described hereinbelow with reference to Table Table1.

[7040] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM483 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7041]

[7042] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 484 (GAM484) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7043] GAM484 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM484 was detected is described hereinabove with reference to Figs. 2-8.

[7044] GAM484 gene, herein designated GAM GENE, and GAM484 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7045] GAM484 gene, herein designated GAM GENE, encodes a GAM484 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM484 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM484 precursor RNA is designated SEQ ID:7649, and is provided hereinbelow with reference to the sequence listing part.

[7046] GAM484 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM484 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7047] An enzyme complex designated DICER COMPLEX, dices the GAM484 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM484 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 29%) nucleotide sequence of GAM484 RNA is designated SEQ ID:7650, and is provided hereinbelow with reference to the sequence listing part.

[7048] GAM484 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM484 target RNA, herein designated GAM TARGET RNA. GAM484 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7049] GAM484 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM484 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM484 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM484 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM484 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7050] The complementary binding of GAM484 RNA, herein designated GAM RNA, to target binding sites on GAM484 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM484 target RNA, herein designated GAM TARGET RNA, into GAM484 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7051] It is appreciated that GAM484 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM484 target genes. The mRNA of each one of this plurality of GAM484 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM484 RNA,

herein designated GAM RNA, and which when bound by GAM484 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM484 target proteins.

[7052] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM484 gene, herein designated GAM GENE, on one or more GAM484 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7053] It is yet further appreciated that specific functions, and accordingly utilities, of GAM484 correlate with, and may be deduced from, the identity of the target genes which

GAM484 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7054] Nucleotide sequences of the GAM484 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM484 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM484 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM484 are further described hereinbelow with reference to Table Table1.

[7055] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM484 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7056]

[7057] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 485 (GAM485) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7058] GAM485 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM485 was detected is described hereinabove with reference to Figs. 2-8.

[7059] GAM485 gene, herein designated GAM GENE, and GAM485 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7060] GAM485 gene, herein designated GAM GENE, encodes a GAM485 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM485 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM485 precursor RNA is designated SEQ ID:7667, and is provided hereinbelow with reference to the sequence listing part.

[7061] GAM485 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM485 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[7062] An enzyme complex designated DICER COMPLEX, dices the GAM485 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM485 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 78%) nucleotide sequence of GAM485 RNA is designated SEQ ID:7668, and is provided hereinbelow with reference to the sequence listing part.

[7063] GAM485 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM485 target RNA, herein designated GAM TARGET RNA.
GAM485 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7064] GAM485 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM485 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM485 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM485 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM485 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7065] The complementary binding of GAM485 RNA, herein designated GAM RNA, to target binding sites on GAM485 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM485 target RNA, herein desig-

nated GAM TARGET RNA, into GAM485 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7066] It is appreciated that GAM485 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM485 target genes. The mRNA of each one of this plurality of GAM485 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM485 RNA, herein designated GAM RNA, and which when bound by GAM485 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM485 target proteins.

[7067] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM485 gene, herein designated GAM GENE, on one or more GAM485 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7068] It is yet further appreciated that specific functions, and accordingly utilities, of GAM485 correlate with, and may be deduced from, the identity of the target genes which GAM485 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7069] Nucleotide sequences of the GAM485 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM485 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM485 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM485 are further described hereinbelow with reference to Table Table1.

[7070] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM485 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[7071]

[7072] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 486 (GAM486) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7073] GAM486 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM486 was detected is described hereinabove with reference to Figs. 2-8.

[7074] GAM486 gene, herein designated GAM GENE, and GAM486 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7075] GAM486 gene, herein designated GAM GENE, encodes a GAM486 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM486 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM486 precursor RNA is designated SEQ ID:7677, and is provided hereinbelow with ref-

erence to the sequence listing part.

[7076] GAM486 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM486 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7077] An enzyme complex designated DICER COMPLEX, dices the GAM486 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM486 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM486 RNA is designated SEQ ID:7678, and is provided hereinbelow with reference to the sequence listing part.

[7078] GAM486 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM486 target RNA, herein designated GAM TARGET RNA.

GAM486 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7079] GAM486 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM486 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM486 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM486 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM486 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7080] The complementary binding of GAM486 RNA, herein designated GAM RNA, to target binding sites on GAM486 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM486 target RNA, herein designated GAM TARGET RNA, into GAM486 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7081] It is appreciated that GAM486 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM486 target genes. The mRNA of each one of this plurality of GAM486 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM486 RNA, herein designated GAM RNA, and which when bound by GAM486 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM486 target proteins.

[7082] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM486 gene, herein designated GAM GENE, on one or more GAM486 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7083] It is yet further appreciated that specific functions, and accordingly utilities, of GAM486 correlate with, and may be deduced from, the identity of the target genes which GAM486 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7084] Nucleotide sequences of the GAM486 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM486 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM486 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM486 are further described hereinbelow with reference to Table Table1.

[7085] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM486 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7086]

[7087] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 487 (GAM487) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7088] GAM487 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM487 was detected is described hereinabove with reference to Figs. 2-8.

[7089] GAM487 gene, herein designated GAM GENE, and GAM487 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[7090] GAM487 gene, herein designated GAM GENE, encodes a GAM487 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM487 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM487 precursor RNA is designated SEQ ID:7689, and is provided hereinbelow with reference to the sequence listing part.

[7091] GAM487 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM487 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7092] An enzyme complex designated DICER COMPLEX, dices the GAM487 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM487 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM487 RNA is designated SEQ ID:7690, and is provided hereinbelow with reference to the sequence listing part.

[7093] GAM487 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM487 target RNA, herein designated GAM TARGET RNA. GAM487 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7094] GAM487 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM487 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM487 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM487 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM487 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7095] The complementary binding of GAM487 RNA, herein designated GAM RNA, to target binding sites on GAM487 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM487 target RNA, herein designated GAM TARGET RNA, into GAM487 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7096] It is appreciated that GAM487 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM487 target genes. The mRNA of each one of this plurality of GAM487 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM487 RNA, herein designated GAM RNA, and which when bound by GAM487 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM487 target proteins.

[7097] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM487 gene, herein designated GAM GENE, on one or more GAM487 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[7098] It is yet further appreciated that specific functions, and accordingly utilities, of GAM487 correlate with, and may be deduced from, the identity of the target genes which GAM487 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7099] Nucleotide sequences of the GAM487 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM487 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM487 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM487 are further described hereinbelow with reference to Table Table1.

[7100] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM487 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7101]

[7102] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

488 (GAM488) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7103] GAM488 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM488 was detected is described hereinabove with reference to Figs. 2-8.

[7104] GAM488 gene, herein designated GAM GENE, and GAM488 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7105] GAM488 gene, herein designated GAM GENE, encodes a GAM488 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM488 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM488 precursor RNA is designated SEQ ID:7704, and is provided hereinbelow with reference to the sequence listing part.

[7106] GAM488 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM488 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7107] An enzyme complex designated DICER COMPLEX, dices the GAM488 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM488 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 23%) nucleotide sequence of GAM488 RNA is designated SEQ ID:7705, and is provided hereinbelow with reference to the sequence listing part.

[7108] GAM488 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM488 target RNA, herein designated GAM TARGET RNA. GAM488 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7109] GAM488 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM488 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM488 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM488 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM488 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7110] The complementary binding of GAM488 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM488 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM488 target RNA, herein designated GAM TARGET RNA, into GAM488 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7111] It is appreciated that GAM488 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM488 target genes. The mRNA of each one of this plurality of GAM488 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM488 RNA, herein designated GAM RNA, and which when bound by GAM488 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM488 target proteins.

[7112] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM488 gene, herein designated GAM GENE, on one or more GAM488 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7113] It is yet further appreciated that specific functions, and accordingly utilities, of GAM488 correlate with, and may be deduced from, the identity of the target genes which GAM488 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7114] Nucleotide sequences of the GAM488 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM488 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM488 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM488 are further described hereinbelow with reference to Table Table1.

[7115] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM488 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7116]

[7117] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 489 (GAM489) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7118] GAM489 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM489 was detected is described hereinabove with reference to Figs. 2-8.

[7119] GAM489 gene, herein designated GAM GENE, and GAM489 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7120] GAM489 gene, herein designated GAM GENE, encodes a GAM489 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM489 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM489 precursor RNA is designated SEQ ID:7719, and is provided hereinbelow with reference to the sequence listing part.

[7121] GAM489 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM489 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7122] An enzyme complex designated DICER COMPLEX, dices the GAM489 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM489 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 79%) nucleotide sequence of GAM489 RNA is designated SEQ ID:7720, and is provided hereinbelow with reference to the sequence listing part.

[7123] GAM489 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM489 target RNA, herein designated GAM TARGET RNA. GAM489 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7124] GAM489 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM489 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM489 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM489 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM489 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7125] The complementary binding of GAM489 RNA, herein designated GAM RNA, to target binding sites on GAM489 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM489 target RNA, herein designated GAM TARGET RNA, into GAM489 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7126] It is appreciated that GAM489 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM489 target genes. The mRNA of each one of this plurality of GAM489 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM489 RNA, herein designated GAM RNA, and which when bound by

GAM489 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM489 target proteins.

[7127] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM489 gene, herein designated GAM GENE, on one or more GAM489 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7128] It is yet further appreciated that specific functions, and accordingly utilities, of GAM489 correlate with, and may be deduced from, the identity of the target genes which GAM489 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[7129] Nucleotide sequences of the GAM489 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM489 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM489 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM489 are further described hereinbelow with reference to Table Table1.

[7130] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM489 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7131]

[7132] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 490 (GAM490) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7133] GAM490 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM490 was detected is described hereinabove with reference to Figs. 2-8.

[7134] GAM490 gene, herein designated GAM GENE, and GAM490 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7135] GAM490 gene, herein designated GAM GENE, encodes a GAM490 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM490 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM490 precursor RNA is designated SEQ ID:7736, and is provided hereinbelow with reference to the sequence listing part.

[7136] GAM490 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM490 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[7137] An enzyme complex designated DICER COMPLEX, dices the GAM490 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM490 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM490 RNA is designated SEQ ID:7737, and is provided hereinbelow with reference to the sequence listing part.

[7138] GAM490 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM490 target RNA, herein designated GAM TARGET RNA. GAM490 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7139] GAM490 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM490 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM490 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM490 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM490 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7140] The complementary binding of GAM490 RNA, herein designated GAM RNA, to target binding sites on GAM490 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM490 target RNA, herein designated GAM TARGET RNA, into GAM490 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7141] It is appreciated that GAM490 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM490 target genes. The mRNA of each one of this plurality of GAM490 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM490 RNA, herein designated GAM RNA, and which when bound by GAM490 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM490 target proteins.

[7142] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM490 gene, herein designated GAM GENE, on one or more GAM490 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7143] It is yet further appreciated that specific functions, and accordingly utilities, of GAM490 correlate with, and may be deduced from, the identity of the target genes which GAM490 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7144] Nucleotide sequences of the GAM490 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM490 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM490 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM490 are further described hereinbelow with reference to Table Table1.

[7145] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM490 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7146]

[7147] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 491 (GAM491) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7148] GAM491 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM491 was detected is described hereinabove with reference to Figs. 2-8.

[7149] GAM491 gene, herein designated GAM GENE, and GAM491 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7150] GAM491 gene, herein designated GAM GENE, encodes a GAM491 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM491 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM491 precursor RNA is designated SEQ ID:7753, and is provided hereinbelow with reference to the sequence listing part.

[7151] GAM491 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM491 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7152] An enzyme complex designated DICER COMPLEX, dices

the GAM491 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM491 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM491 RNA is designated SEQ ID:7754, and is provided hereinbelow with reference to the sequence listing part.

[7153] GAM491 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM491 target RNA, herein designated GAM TARGET RNA. GAM491 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7154] GAM491 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM491 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM491

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM491 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM491 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7155] The complementary binding of GAM491 RNA, herein designated GAM RNA, to target binding sites on GAM491 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM491 target RNA, herein designated GAM TARGET RNA, into GAM491 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7156] It is appreciated that GAM491 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM491 target genes. The mRNA of each one of this plurality of GAM491 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM491 RNA, herein designated GAM RNA, and which when bound by GAM491 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM491 target proteins.

[7157] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM491 gene, herein designated GAM GENE, on one or more GAM491 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7158] It is yet further appreciated that specific functions, and accordingly utilities, of GAM491 correlate with, and may be deduced from, the identity of the target genes which GAM491 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7159] Nucleotide sequences of the GAM491 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM491 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM491 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM491 are further described hereinbelow with reference to Table Table1.

[7160] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM491 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7161]

[7162] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 492 (GAM492) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7163] GAM492 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM492 was detected is described hereinabove with reference to Figs. 2-8.

[7164] GAM492 gene, herein designated GAM GENE, and GAM492 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7165] GAM492 gene, herein designated GAM GENE, encodes a GAM492 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM492 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM492 precursor RNA is designated SEQ ID:7778, and is provided hereinbelow with reference to the sequence listing part.

[7166] GAM492 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM492 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7167] An enzyme complex designated DICER COMPLEX, dices the GAM492 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM492 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM492 RNA is designated SEQ ID:7779, and is provided hereinbelow with reference to the sequence listing part.

[7168] GAM492 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM492 target RNA, herein designated GAM TARGET RNA. GAM492 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7169] GAM492 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM492 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM492 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM492 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM492 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[7170] The complementary binding of GAM492 RNA, herein designated GAM RNA, to target binding sites on GAM492 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM492 target RNA, herein designated GAM TARGET RNA, into GAM492 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7171] It is appreciated that GAM492 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM492 target genes. The mRNA of each one of this plurality of GAM492 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM492 RNA, herein designated GAM RNA, and which when bound by GAM492 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM492 target proteins.

[7172] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM492 gene, herein designated GAM GENE, on one or

more GAM492 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7173] It is yet further appreciated that specific functions, and accordingly utilities, of GAM492 correlate with, and may be deduced from, the identity of the target genes which GAM492 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7174] Nucleotide sequences of the GAM492 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM492 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM492 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM492 are further de-

scribed hereinbelow with reference to Table Table1.

[7175] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM492 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7176]

[7177] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 493 (GAM493) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7178] GAM493 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM493 was detected is described hereinabove with reference to Figs. 2-8.

[7179] GAM493 gene, herein designated GAM GENE, and GAM493 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7180] GAM493 gene, herein designated GAM GENE, encodes a GAM493 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM493 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM493 precursor RNA is designated SEQ ID:7803, and is provided hereinbelow with reference to the sequence listing part.

[7181] GAM493 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM493 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7182] An enzyme complex designated DICER COMPLEX, dices the GAM493 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM493 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 22%) nucleotide sequence of GAM493 RNA is designated SEQ ID:7804, and is provided hereinbelow with reference to the sequence listing part.

[7183] GAM493 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM493 target RNA, herein designated GAM TARGET RNA. GAM493 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7184] GAM493 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM493 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM493 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM493 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM493 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7185] The complementary binding of GAM493 RNA, herein designated GAM RNA, to target binding sites on GAM493 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM493 target RNA, herein designated GAM TARGET RNA, into GAM493 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7186] It is appreciated that GAM493 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM493 target genes. The mRNA of each one of this plurality of GAM493 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM493 RNA, herein designated GAM RNA, and which when bound by GAM493 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM493 target proteins.

[7187] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM493 gene, herein designated GAM GENE, on one or more GAM493 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7188] It is yet further appreciated that specific functions, and accordingly utilities, of GAM493 correlate with, and may

be deduced from, the identity of the target genes which GAM493 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7189] Nucleotide sequences of the GAM493 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM493 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM493 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM493 are further described hereinbelow with reference to Table Table1.

[7190] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM493 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7191]

[7192] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 494 (GAM494) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7193] GAM494 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM494 was detected is described hereinabove with reference to Figs. 2-8.

[7194] GAM494 gene, herein designated GAM GENE, and GAM494 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7195] GAM494 gene, herein designated GAM GENE, encodes a GAM494 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM494 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM494 precursor RNA is designated SEQ ID:7821, and is provided hereinbelow with reference to the sequence listing part.

[7196] GAM494 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM494 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7197] An enzyme complex designated DICER COMPLEX, dices the GAM494 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM494 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 76%) nucleotide sequence of GAM494 RNA is designated SEQ ID:7822, and is provided hereinbelow with reference to the sequence listing part.

[7198] GAM494 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM494 target RNA, herein designated GAM TARGET RNA. GAM494 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7199] GAM494 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM494 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM494 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM494 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM494 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7200] The complementary binding of GAM494 RNA, herein designated GAM RNA, to target binding sites on GAM494 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM494 target RNA, herein designated GAM TARGET RNA, into GAM494 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7201] It is appreciated that GAM494 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM494 target genes. The mRNA of each one of this plurality of GAM494 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM494 RNA, herein designated GAM RNA, and which when bound by GAM494 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM494 target proteins.

[7202] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM494 gene, herein designated GAM GENE, on one or more GAM494 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7203] It is yet further appreciated that specific functions, and accordingly utilities, of GAM494 correlate with, and may be deduced from, the identity of the target genes which GAM494 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7204] Nucleotide sequences of the GAM494 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM494 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM494 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM494 are further described hereinbelow with reference to Table Table1.

[7205] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM494 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7206]

[7207] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 495 (GAM495) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7208] GAM495 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM495 was detected is described hereinabove with reference to Figs. 2-8.

[7209] GAM495 gene, herein designated GAM GENE, and GAM495 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7210] GAM495 gene, herein designated GAM GENE, encodes a GAM495 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM495 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM495 precursor RNA is desig-

nated SEQ ID:7835, and is provided hereinbelow with reference to the sequence listing part.

[7211] GAM495 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM495 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7212] An enzyme complex designated DICER COMPLEX, dices the GAM495 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM495 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM495 RNA is designated SEQ ID:7836, and is provided hereinbelow with reference to the sequence listing part.

[7213] GAM495 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM495 target RNA, herein designated GAM TARGET RNA. GAM495 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7214] GAM495 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM495 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM495 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM495 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM495

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7215] The complementary binding of GAM495 RNA, herein designated GAM RNA, to target binding sites on GAM495 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM495 target RNA, herein designated GAM TARGET RNA, into GAM495 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7216] It is appreciated that GAM495 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM495 target genes. The mRNA of each one of this plurality of GAM495 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM495 RNA, herein designated GAM RNA, and which when bound by GAM495 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM495 target proteins.

[7217] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM495 gene, herein designated GAM GENE, on one or more GAM495 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7218] It is yet further appreciated that specific functions, and accordingly utilities, of GAM495 correlate with, and may be deduced from, the identity of the target genes which GAM495 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7219] Nucleotide sequences of the GAM495 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM495 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM495 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM495 are further described hereinbelow with reference to Table Table1.

[7220] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM495 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7221]

[7222] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 496 (GAM496) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7223] GAM496 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM496 was detected is described hereinabove with reference to Figs. 2-8.

[7224] GAM496 gene, herein designated GAM GENE, and

GAM496 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7225] GAM496 gene, herein designated GAM GENE, encodes a GAM496 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM496 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM496 precursor RNA is designated SEQ ID:7839, and is provided hereinbelow with reference to the sequence listing part.

[7226] GAM496 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM496 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7227] An enzyme complex designated DICER COMPLEX, dices the GAM496 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM496 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM496 RNA is designated SEQ ID:7840, and is provided hereinbelow with reference to the sequence listing part.

[7228] GAM496 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM496 target RNA, herein designated GAM TARGET RNA. GAM496 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7229] GAM496 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM496 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM496 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM496 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM496 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7230] The complementary binding of GAM496 RNA, herein designated GAM RNA, to target binding sites on GAM496 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM496 target RNA, herein designated GAM TARGET RNA, into GAM496 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7231] It is appreciated that GAM496 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM496 target genes. The mRNA of each one of this plurality of GAM496 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM496 RNA, herein designated GAM RNA, and which when bound by GAM496 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM496 target proteins.

[7232] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM496 gene, herein designated GAM GENE, on one or more GAM496 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7233] It is yet further appreciated that specific functions, and accordingly utilities, of GAM496 correlate with, and may be deduced from, the identity of the target genes which GAM496 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7234] Nucleotide sequences of the GAM496 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM496 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM496 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM496 are further described hereinbelow with reference to Table Table1.

[7235] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM496 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7236]

[7237] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 497 (GAM497) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7238] GAM497 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM497 was detected is described hereinabove with reference to Figs. 2-8.

[7239] GAM497 gene, herein designated GAM GENE, and GAM497 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7240] GAM497 gene, herein designated GAM GENE, encodes a GAM497 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM497 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM497 precursor RNA is designated SEQ ID:7858, and is provided hereinbelow with reference to the sequence listing part.

[7241] GAM497 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM497 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7242] An enzyme complex designated DICER COMPLEX, dices the GAM497 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM497 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 83%) nucleotide sequence of GAM497 RNA is designated SEQ ID:7859, and is provided hereinbelow with reference to the sequence listing part.

[7243] GAM497 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM497 target RNA, herein designated GAM TARGET RNA. GAM497 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7244] GAM497 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM497 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM497 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM497 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM497 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7245] The complementary binding of GAM497 RNA, herein designated GAM RNA, to target binding sites on GAM497 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM497 target RNA, herein designated GAM TARGET RNA, into GAM497 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7246] It is appreciated that GAM497 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM497 target genes. The mRNA of each one of this plurality of GAM497 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM497 RNA, herein designated GAM RNA, and which when bound by GAM497 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM497 target proteins.

[7247] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM497 gene, herein designated GAM GENE, on one or more GAM497 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7248] It is yet further appreciated that specific functions, and accordingly utilities, of GAM497 correlate with, and may be deduced from, the identity of the target genes which GAM497 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7249] Nucleotide sequences of the GAM497 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM497 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM497 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM497 are further described hereinbelow with reference to Table Table1.

[7250] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM497 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7251]

[7252] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 498 (GAM498) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7253] GAM498 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM498 was detected is described hereinabove with reference to Figs. 2-8.

[7254] GAM498 gene, herein designated GAM GENE, and GAM498 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7255] GAM498 gene, herein designated GAM GENE, encodes a GAM498 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM498 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM498 precursor RNA is designated SEQ ID:7876, and is provided hereinbelow with reference to the sequence listing part.

[7256] GAM498 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM498 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7257] An enzyme complex designated DICER COMPLEX, dices the GAM498 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM498 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM498 RNA is designated SEQ ID:7877, and is provided hereinbelow with reference to the sequence listing part.

[7258] GAM498 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM498 target RNA, herein designated GAM TARGET RNA. GAM498 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7259] GAM498 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM498 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM498 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM498 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM498 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7260] The complementary binding of GAM498 RNA, herein designated GAM RNA, to target binding sites on GAM498 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM498 target RNA, herein designated GAM TARGET RNA, into GAM498 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7261] It is appreciated that GAM498 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM498 target genes. The mRNA of each one of this plurality of GAM498 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM498 RNA,

herein designated GAM RNA, and which when bound by GAM498 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM498 target proteins.

[7262] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM498 gene, herein designated GAM GENE, on one or more GAM498 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7263] It is yet further appreciated that specific functions, and accordingly utilities, of GAM498 correlate with, and may be deduced from, the identity of the target genes which

GAM498 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7264] Nucleotide sequences of the GAM498 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM498 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM498 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM498 are further described hereinbelow with reference to Table Table1.

[7265] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM498 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7266]

[7267] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 499 (GAM499) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7268] GAM499 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM499 was detected is described hereinabove with reference to Figs. 2-8.

[7269] GAM499 gene, herein designated GAM GENE, and GAM499 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7270] GAM499 gene, herein designated GAM GENE, encodes a GAM499 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM499 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM499 precursor RNA is designated SEQ ID:7890, and is provided hereinbelow with reference to the sequence listing part.

[7271] GAM499 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM499 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[7272] An enzyme complex designated DICER COMPLEX, dices the GAM499 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM499 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 61%) nucleotide sequence of GAM499 RNA is designated SEQ ID:7891, and is provided hereinbelow with reference to the sequence listing part.

[7273] GAM499 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM499 target RNA, herein designated GAM TARGET RNA.
GAM499 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7274] GAM499 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM499 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM499 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM499 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM499 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7275] The complementary binding of GAM499 RNA, herein designated GAM RNA, to target binding sites on GAM499 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM499 target RNA, herein desig-

nated GAM TARGET RNA, into GAM499 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7276] It is appreciated that GAM499 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM499 target genes. The mRNA of each one of this plurality of GAM499 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM499 RNA, herein designated GAM RNA, and which when bound by GAM499 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM499 target proteins.

[7277] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM499 gene, herein designated GAM GENE, on one or more GAM499 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7278] It is yet further appreciated that specific functions, and accordingly utilities, of GAM499 correlate with, and may be deduced from, the identity of the target genes which GAM499 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7279] Nucleotide sequences of the GAM499 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM499 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM499 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM499 are further described hereinbelow with reference to Table Table1.

[7280] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM499 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[7281]

[7282] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 500 (GAM500) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7283] GAM500 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM500 was detected is described hereinabove with reference to Figs. 2-8.

[7284] GAM500 gene, herein designated GAM GENE, and GAM500 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7285] GAM500 gene, herein designated GAM GENE, encodes a GAM500 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM500 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM500 precursor RNA is designated SEQ ID:7896, and is provided hereinbelow with ref-

erence to the sequence listing part.

[7286] GAM500 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM500 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7287] An enzyme complex designated DICER COMPLEX, dices the GAM500 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM500 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 78%) nucleotide sequence of GAM500 RNA is designated SEQ ID:7897, and is provided hereinbelow with reference to the sequence listing part.

[7288] GAM500 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM500 target RNA, herein designated GAM TARGET RNA.

GAM500 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7289] GAM500 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM500 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM500 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM500 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM500 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7290] The complementary binding of GAM500 RNA, herein designated GAM RNA, to target binding sites on GAM500 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM500 target RNA, herein designated GAM TARGET RNA, into GAM500 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7291] It is appreciated that GAM500 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM500 target genes. The mRNA of each one of this plurality of GAM500 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM500 RNA, herein designated GAM RNA, and which when bound by GAM500 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM500 target proteins.

[7292] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM500 gene, herein designated GAM GENE, on one or more GAM500 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7293] It is yet further appreciated that specific functions, and accordingly utilities, of GAM500 correlate with, and may be deduced from, the identity of the target genes which GAM500 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7294] Nucleotide sequences of the GAM500 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM500 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM500 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM500 are further described hereinbelow with reference to Table Table1.

[7295] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM500 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7296]

[7297] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 501 (GAM501) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7298] GAM501 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM501 was detected is described hereinabove with reference to Figs. 2-8.

[7299] GAM501 gene, herein designated GAM GENE, and GAM501 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[7300] GAM501 gene, herein designated GAM GENE, encodes a GAM501 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM501 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM501 precursor RNA is designated SEQ ID:7909, and is provided hereinbelow with reference to the sequence listing part.

[7301] GAM501 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM501 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7302] An enzyme complex designated DICER COMPLEX, dices the GAM501 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM501 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 23%) nucleotide sequence of GAM501 RNA is designated SEQ ID:7910, and is provided hereinbelow with reference to the sequence listing part.

[7303] GAM501 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM501 target RNA, herein designated GAM TARGET RNA. GAM501 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7304] GAM501 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM501 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM501 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM501 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM501 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7305] The complementary binding of GAM501 RNA, herein designated GAM RNA, to target binding sites on GAM501 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM501 target RNA, herein designated GAM TARGET RNA, into GAM501 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7306] It is appreciated that GAM501 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM501 target genes. The mRNA of each one of this plurality of GAM501 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM501 RNA, herein designated GAM RNA, and which when bound by GAM501 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM501 target proteins.

[7307] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM501 gene, herein designated GAM GENE, on one or more GAM501 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[7308] It is yet further appreciated that specific functions, and accordingly utilities, of GAM501 correlate with, and may be deduced from, the identity of the target genes which GAM501 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7309] Nucleotide sequences of the GAM501 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM501 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM501 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM501 are further described hereinbelow with reference to Table Table1.

[7310] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM501 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7311]

[7312] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

502 (GAM502) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7313] GAM502 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM502 was detected is described hereinabove with reference to Figs. 2-8.

[7314] GAM502 gene, herein designated GAM GENE, and GAM502 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7315] GAM502 gene, herein designated GAM GENE, encodes a GAM502 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM502 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM502 precursor RNA is designated SEQ ID:7918, and is provided hereinbelow with reference to the sequence listing part.

[7316] GAM502 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM502 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7317] An enzyme complex designated DICER COMPLEX, dices the GAM502 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM502 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM502 RNA is designated SEQ ID:7919, and is provided hereinbelow with reference to the sequence listing part.

[7318] GAM502 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM502 target RNA, herein designated GAM TARGET RNA. GAM502 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7319] GAM502 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM502 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM502 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM502 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM502 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7320] The complementary binding of GAM502 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM502 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM502 target RNA, herein designated GAM TARGET RNA, into GAM502 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7321] It is appreciated that GAM502 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM502 target genes. The mRNA of each one of this plurality of GAM502 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM502 RNA, herein designated GAM RNA, and which when bound by GAM502 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM502 target proteins.

[7322] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM502 gene, herein designated GAM GENE, on one or more GAM502 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7323] It is yet further appreciated that specific functions, and accordingly utilities, of GAM502 correlate with, and may be deduced from, the identity of the target genes which GAM502 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7324] Nucleotide sequences of the GAM502 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM502 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM502 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM502 are further described hereinbelow with reference to Table Table1.

[7325] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM502 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7326]

[7327] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 503 (GAM503) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7328] GAM503 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM503 was detected is described hereinabove with reference to Figs. 2-8.

[7329] GAM503 gene, herein designated GAM GENE, and GAM503 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7330] GAM503 gene, herein designated GAM GENE, encodes a GAM503 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM503 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM503 precursor RNA is designated SEQ ID:7924, and is provided hereinbelow with reference to the sequence listing part.

[7331] GAM503 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM503 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7332] An enzyme complex designated DICER COMPLEX, dices the GAM503 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM503 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 82%) nucleotide sequence of GAM503 RNA is designated SEQ ID:7925, and is provided hereinbelow with reference to the sequence listing part.

[7333] GAM503 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM503 target RNA, herein designated GAM TARGET RNA. GAM503 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7334] GAM503 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM503 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM503 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM503 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM503 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7335] The complementary binding of GAM503 RNA, herein designated GAM RNA, to target binding sites on GAM503 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM503 target RNA, herein designated GAM TARGET RNA, into GAM503 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7336] It is appreciated that GAM503 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM503 target genes. The mRNA of each one of this plurality of GAM503 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM503 RNA, herein designated GAM RNA, and which when bound by

GAM503 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM503 target proteins.

[7337] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM503 gene, herein designated GAM GENE, on one or more GAM503 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7338] It is yet further appreciated that specific functions, and accordingly utilities, of GAM503 correlate with, and may be deduced from, the identity of the target genes which GAM503 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[7339] Nucleotide sequences of the GAM503 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM503 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM503 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM503 are further described hereinbelow with reference to Table Table1.

[7340] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM503 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7341]

[7342] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 504 (GAM504) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7343] GAM504 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM504 was detected is described hereinabove with reference to Figs. 2-8.

[7344] GAM504 gene, herein designated GAM GENE, and GAM504 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7345] GAM504 gene, herein designated GAM GENE, encodes a GAM504 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM504 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM504 precursor RNA is designated SEQ ID:7952, and is provided hereinbelow with reference to the sequence listing part.

[7346] GAM504 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM504 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[7347] An enzyme complex designated DICER COMPLEX, dices the GAM504 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM504 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM504 RNA is designated SEQ ID:7953, and is provided hereinbelow with reference to the sequence listing part.

[7348] GAM504 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM504 target RNA, herein designated GAM TARGET RNA. GAM504 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7349] GAM504 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM504 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM504 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM504 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM504 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7350] The complementary binding of GAM504 RNA, herein designated GAM RNA, to target binding sites on GAM504 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM504 target RNA, herein designated GAM TARGET RNA, into GAM504 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7351] It is appreciated that GAM504 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM504 target genes. The mRNA of each one of this plurality of GAM504 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM504 RNA, herein designated GAM RNA, and which when bound by GAM504 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM504 target proteins.

[7352] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM504 gene, herein designated GAM GENE, on one or more GAM504 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7353] It is yet further appreciated that specific functions, and accordingly utilities, of GAM504 correlate with, and may be deduced from, the identity of the target genes which GAM504 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7354] Nucleotide sequences of the GAM504 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM504 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM504 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM504 are further described hereinbelow with reference to Table Table1.

[7355] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM504 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7356]

[7357] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 505 (GAM505) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7358] GAM505 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM505 was detected is described hereinabove with reference to Figs. 2-8.

[7359] GAM505 gene, herein designated GAM GENE, and GAM505 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7360] GAM505 gene, herein designated GAM GENE, encodes a GAM505 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM505 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM505 precursor RNA is designated SEQ ID:7992, and is provided hereinbelow with reference to the sequence listing part.

[7361] GAM505 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM505 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7362] An enzyme complex designated DICER COMPLEX, dices the GAM505 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM505 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM505 RNA is designated SEQ ID:7993, and is provided hereinbelow with reference to the sequence listing part.

[7363] GAM505 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM505

target RNA, herein designated GAM TARGET RNA.

GAM505 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7364] GAM505 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM505 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM505 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM505 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM505 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7365] The complementary binding of GAM505 RNA, herein designated GAM RNA, to target binding sites on GAM505 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM505 target RNA, herein designated GAM TARGET RNA, into GAM505 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7366] It is appreciated that GAM505 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM505 target genes. The mRNA of each one of this plurality of GAM505 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM505 RNA, herein designated GAM RNA, and which when bound by GAM505 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM505 target proteins.

[7367] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM505 gene, herein designated GAM GENE, on one or more GAM505 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7368] It is yet further appreciated that specific functions, and accordingly utilities, of GAM505 correlate with, and may be deduced from, the identity of the target genes which GAM505 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7369] Nucleotide sequences of the GAM505 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM505 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM505 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM505 are further described hereinbelow with reference to Table Table1.

[7370] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM505 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7371]

[7372] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 506 (GAM506) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7373] GAM506 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM506 was detected is described hereinabove with reference to Figs. 2-8.

[7374] GAM506 gene, herein designated GAM GENE, and GAM506 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7375] GAM506 gene, herein designated GAM GENE, encodes a GAM506 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM506 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM506 precursor RNA is designated SEQ ID:8026, and is provided hereinbelow with reference to the sequence listing part.

[7376] GAM506 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM506 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7377] An enzyme complex designated DICER COMPLEX, dices the GAM506 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM506 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 23%) nucleotide sequence of GAM506 RNA is designated SEQ ID:8027, and is provided hereinbelow with reference to the sequence listing part.

[7378] GAM506 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM506 target RNA, herein designated GAM TARGET RNA. GAM506 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7379] GAM506 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM506 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM506 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM506 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM506 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7380] The complementary binding of GAM506 RNA, herein designated GAM RNA, to target binding sites on GAM506 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM506 target RNA, herein designated GAM TARGET RNA, into GAM506 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7381] It is appreciated that GAM506 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM506 target genes. The mRNA of each one of this plu-

rality of GAM506 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM506 RNA, herein designated GAM RNA, and which when bound by GAM506 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM506 target proteins.

[7382] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM506 gene, herein designated GAM GENE, on one or more GAM506 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7383] It is yet further appreciated that specific functions, and accordingly utilities, of GAM506 correlate with, and may be deduced from, the identity of the target genes which GAM506 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7384] Nucleotide sequences of the GAM506 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM506 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM506 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM506 are further described hereinbelow with reference to Table Table1.

[7385] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM506 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7386]

[7387] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 507 (GAM507) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[7388] GAM507 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM507 was detected is described hereinabove with reference to Figs. 2-8.

[7389] GAM507 gene, herein designated GAM GENE, and GAM507 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7390] GAM507 gene, herein designated GAM GENE, encodes a GAM507 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM507 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM507 precursor RNA is designated SEQ ID:8051, and is provided hereinbelow with reference to the sequence listing part.

[7391] GAM507 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM507 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7392] An enzyme complex designated DICER COMPLEX, dices the GAM507 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM507 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM507 RNA is designated SEQ ID:8052, and is provided hereinbelow with reference to the sequence listing part.

[7393] GAM507 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM507 target RNA, herein designated GAM TARGET RNA.
GAM507 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[7394] GAM507 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM507 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM507 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM507 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM507 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7395] The complementary binding of GAM507 RNA, herein designated GAM RNA, to target binding sites on GAM507 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM507 target RNA, herein designated GAM TARGET RNA, into GAM507 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7396] It is appreciated that GAM507 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM507 target genes. The mRNA of each one of this plurality of GAM507 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM507 RNA, herein designated GAM RNA, and which when bound by GAM507 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM507 target proteins.

[7397] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM507 gene, herein designated GAM GENE, on one or more GAM507 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7398] It is yet further appreciated that specific functions, and accordingly utilities, of GAM507 correlate with, and may be deduced from, the identity of the target genes which GAM507 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7399] Nucleotide sequences of the GAM507 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM507 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM507 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM507 are further described hereinbelow with reference to Table Table1.

[7400] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM507 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7401]

[7402] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 508 (GAM508) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7403] GAM508 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM508 was detected is described hereinabove with reference to Figs. 2-8.

[7404] GAM508 gene, herein designated GAM GENE, and GAM508 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7405] GAM508 gene, herein designated GAM GENE, encodes a GAM508 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM508 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM508 precursor RNA is designated SEQ ID:8071, and is provided hereinbelow with reference to the sequence listing part.

[7406] GAM508 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM508 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7407] An enzyme complex designated DICER COMPLEX, dices the GAM508 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM508 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of

GAM508 RNA is designated SEQ ID:8072, and is provided hereinbelow with reference to the sequence listing part.

[7408] GAM508 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM508 target RNA, herein designated GAM TARGET RNA. GAM508 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7409] GAM508 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM508 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM508 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM508 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM508 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7410] The complementary binding of GAM508 RNA, herein designated GAM RNA, to target binding sites on GAM508 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM508 target RNA, herein designated GAM TARGET RNA, into GAM508 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7411] It is appreciated that GAM508 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM508 target genes. The mRNA of each one of this plurality of GAM508 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM508 RNA, herein designated GAM RNA, and which when bound by GAM508 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM508 target proteins.

[7412] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM508 gene, herein designated GAM GENE, on one or more GAM508 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7413] It is yet further appreciated that specific functions, and accordingly utilities, of GAM508 correlate with, and may be deduced from, the identity of the target genes which GAM508 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7414] Nucleotide sequences of the GAM508 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM508 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM508 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM508 are further described hereinbelow with reference to Table Table1.

[7415] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM508 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7416]

[7417] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 509 (GAM509) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7418] GAM509 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM509 was detected is described hereinabove

with reference to Figs. 2-8.

[7419] GAM509 gene, herein designated GAM GENE, and GAM509 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7420] GAM509 gene, herein designated GAM GENE, encodes a GAM509 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM509 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM509 precursor RNA is designated SEQ ID:8091, and is provided hereinbelow with reference to the sequence listing part.

[7421] GAM509 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM509 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7422] An enzyme complex designated DICER COMPLEX, dices the GAM509 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM509 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM509 RNA is designated SEQ ID:8092, and is provided hereinbelow with reference to the sequence listing part.

[7423] GAM509 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM509 target RNA, herein designated GAM TARGET RNA. GAM509 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7424] GAM509 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM509 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM509 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM509 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM509 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7425] The complementary binding of GAM509 RNA, herein designated GAM RNA, to target binding sites on GAM509 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM509 target RNA, herein designated GAM TARGET RNA, into GAM509 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[7426] It is appreciated that GAM509 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM509 target genes. The mRNA of each one of this plurality of GAM509 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM509 RNA, herein designated GAM RNA, and which when bound by GAM509 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM509 target proteins.

[7427] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM509 gene, herein designated GAM GENE, on one or more GAM509 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7428] It is yet further appreciated that specific functions, and accordingly utilities, of GAM509 correlate with, and may be deduced from, the identity of the target genes which GAM509 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7429] Nucleotide sequences of the GAM509 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM509 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM509 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM509 are further described hereinbelow with reference to Table Table1.

[7430] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM509 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7431]

[7432] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 510 (GAM510) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7433] GAM510 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM510 was detected is described hereinabove with reference to Figs. 2-8.

[7434] GAM510 gene, herein designated GAM GENE, and GAM510 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7435] GAM510 gene, herein designated GAM GENE, encodes a GAM510 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM510 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM510 precursor RNA is designated SEQ ID:8109, and is provided hereinbelow with reference to the sequence listing part.

[7436] GAM510 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM510 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7437] An enzyme complex designated DICER COMPLEX, dices the GAM510 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM510 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 33%) nucleotide sequence of GAM510 RNA is designated SEQ ID:8110, and is provided hereinbelow with reference to the sequence listing part.

[7438] GAM510 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM510 target RNA, herein designated GAM TARGET RNA.

GAM510 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7439] GAM510 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM510 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM510 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM510 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM510 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7440] The complementary binding of GAM510 RNA, herein designated GAM RNA, to target binding sites on GAM510 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM510 target RNA, herein designated GAM TARGET RNA, into GAM510 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7441] It is appreciated that GAM510 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM510 target genes. The mRNA of each one of this plurality of GAM510 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM510 RNA, herein designated GAM RNA, and which when bound by GAM510 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM510 target proteins.

[7442] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM510 gene, herein designated GAM GENE, on one or more GAM510 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7443] It is yet further appreciated that specific functions, and accordingly utilities, of GAM510 correlate with, and may be deduced from, the identity of the target genes which GAM510 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7444] Nucleotide sequences of the GAM510 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM510 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM510 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM510 are further described hereinbelow with reference to Table Table1.

[7445] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM510 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7446]

[7447] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 511 (GAM511) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7448] GAM511 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM511 was detected is described hereinabove with reference to Figs. 2-8.

[7449] GAM511 gene, herein designated GAM GENE, and GAM511 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7450] GAM511 gene, herein designated GAM GENE, encodes a

GAM511 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM511 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM511 precursor RNA is designated SEQ ID:8136, and is provided hereinbelow with reference to the sequence listing part.

[7451] GAM511 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM511 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7452] An enzyme complex designated DICER COMPLEX, dices the GAM511 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM511 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM511 RNA is designated SEQ ID:8137, and is provided hereinbelow with reference to the sequence listing part.

[7453] GAM511 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM511 target RNA, herein designated GAM TARGET RNA. GAM511 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7454] GAM511 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM511 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM511 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM511 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM511 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7455] The complementary binding of GAM511 RNA, herein designated GAM RNA, to target binding sites on GAM511 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM511 target RNA, herein designated GAM TARGET RNA, into GAM511 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7456] It is appreciated that GAM511 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM511 target genes. The mRNA of each one of this plurality of GAM511 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM511 RNA, herein designated GAM RNA, and which when bound by GAM511 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM511 target proteins.

[7457] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM511 gene, herein designated GAM GENE, on one or more GAM511 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7458] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM511 correlate with, and may be deduced from, the identity of the target genes which GAM511 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7459] Nucleotide sequences of the GAM511 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM511 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM511 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM511 are further described hereinbelow with reference to Table Table1.

[7460] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM511 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7461]

[7462] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 512 (GAM512) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[7463] GAM512 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM512 was detected is described hereinabove with reference to Figs. 2-8.

[7464] GAM512 gene, herein designated GAM GENE, and GAM512 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7465] GAM512 gene, herein designated GAM GENE, encodes a GAM512 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM512 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM512 precursor RNA is designated SEQ ID:8149, and is provided hereinbelow with reference to the sequence listing part.

[7466] GAM512 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM512 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7467] An enzyme complex designated DICER COMPLEX, dices the GAM512 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM512 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 68%) nucleotide sequence of GAM512 RNA is designated SEQ ID:8150, and is provided hereinbelow with reference to the sequence listing part.

[7468] GAM512 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM512 target RNA, herein designated GAM TARGET RNA. GAM512 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7469] GAM512 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM512 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM512 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM512 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM512 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7470] The complementary binding of GAM512 RNA, herein designated GAM RNA, to target binding sites on GAM512 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM512 target RNA, herein designated GAM TARGET RNA, into GAM512 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7471] It is appreciated that GAM512 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM512 target genes. The mRNA of each one of this plurality of GAM512 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM512 RNA, herein designated GAM RNA, and which when bound by GAM512 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM512 target proteins.

[7472] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM512 gene, herein designated GAM GENE, on one or more GAM512 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7473] It is yet further appreciated that specific functions, and accordingly utilities, of GAM512 correlate with, and may be deduced from, the identity of the target genes which GAM512 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7474] Nucleotide sequences of the GAM512 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM512 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM512 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM512 are further described hereinbelow with reference to Table Table1.

[7475] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM512 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7476]

[7477] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 513 (GAM513) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7478] GAM513 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM513 was detected is described hereinabove with reference to Figs. 2-8.

[7479] GAM513 gene, herein designated GAM GENE, and GAM513 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7480] GAM513 gene, herein designated GAM GENE, encodes a GAM513 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM513 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM513 precursor RNA is designated SEQ ID:8162, and is provided hereinbelow with reference to the sequence listing part.

[7481] GAM513 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM513 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7482] An enzyme complex designated DICER COMPLEX, dices the GAM513 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM513 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 80%) nucleotide sequence of GAM513 RNA is designated SEQ ID:8163, and is provided

hereinbelow with reference to the sequence listing part.

[7483] GAM513 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM513 target RNA, herein designated GAM TARGET RNA. GAM513 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7484] GAM513 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM513 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM513 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM513 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM513 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7485] The complementary binding of GAM513 RNA, herein designated GAM RNA, to target binding sites on GAM513 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM513 target RNA, herein designated GAM TARGET RNA, into GAM513 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7486] It is appreciated that GAM513 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM513 target genes. The mRNA of each one of this plurality of GAM513 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM513 RNA, herein designated GAM RNA, and which when bound by GAM513 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM513 tar-

get proteins.

[7487] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM513 gene, herein designated GAM GENE, on one or more GAM513 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7488] It is yet further appreciated that specific functions, and accordingly utilities, of GAM513 correlate with, and may be deduced from, the identity of the target genes which GAM513 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7489] Nucleotide sequences of the GAM513 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM513 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM513 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM513 are further described hereinbelow with reference to Table Table1.

[7490] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM513 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7491]

[7492] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 514 (GAM514) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7493] GAM514 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM514 was detected is described hereinabove with reference to Figs. 2-8.

[7494] GAM514 gene, herein designated GAM GENE, and GAM514 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7495] GAM514 gene, herein designated GAM GENE, encodes a GAM514 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM514 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM514 precursor RNA is designated SEQ ID:8187, and is provided hereinbelow with reference to the sequence listing part.

[7496] GAM514 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM514 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7497] An enzyme complex designated DICER COMPLEX, dices

the GAM514 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM514 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 78%) nucleotide sequence of GAM514 RNA is designated SEQ ID:8188, and is provided hereinbelow with reference to the sequence listing part.

[7498] GAM514 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM514 target RNA, herein designated GAM TARGET RNA. GAM514 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7499] GAM514 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM514 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM514

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM514 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM514 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7500] The complementary binding of GAM514 RNA, herein designated GAM RNA, to target binding sites on GAM514 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM514 target RNA, herein designated GAM TARGET RNA, into GAM514 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7501] It is appreciated that GAM514 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM514 target genes. The mRNA of each one of this plurality of GAM514 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM514 RNA, herein designated GAM RNA, and which when bound by GAM514 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM514 target proteins.

[7502] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM514 gene, herein designated GAM GENE, on one or more GAM514 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7503] It is yet further appreciated that specific functions, and accordingly utilities, of GAM514 correlate with, and may be deduced from, the identity of the target genes which GAM514 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7504] Nucleotide sequences of the GAM514 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM514 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM514 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM514 are further described hereinbelow with reference to Table Table1.

[7505] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM514 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7506]

[7507] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 515 (GAM515) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7508] GAM515 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM515 was detected is described hereinabove with reference to Figs. 2-8.

[7509] GAM515 gene, herein designated GAM GENE, and GAM515 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7510] GAM515 gene, herein designated GAM GENE, encodes a GAM515 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM515 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM515 precursor RNA is designated SEQ ID:8210, and is provided hereinbelow with reference to the sequence listing part.

[7511] GAM515 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM515 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7512] An enzyme complex designated DICER COMPLEX, dices the GAM515 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM515 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 50%) nucleotide sequence of GAM515 RNA is designated SEQ ID:8211, and is provided hereinbelow with reference to the sequence listing part.

[7513] GAM515 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM515 target RNA, herein designated GAM TARGET RNA. GAM515 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7514] GAM515 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM515 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM515 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM515 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM515 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[7515] The complementary binding of GAM515 RNA, herein designated GAM RNA, to target binding sites on GAM515 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM515 target RNA, herein designated GAM TARGET RNA, into GAM515 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7516] It is appreciated that GAM515 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM515 target genes. The mRNA of each one of this plurality of GAM515 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM515 RNA, herein designated GAM RNA, and which when bound by GAM515 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM515 target proteins.

[7517] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM515 gene, herein designated GAM GENE, on one or

more GAM515 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7518] It is yet further appreciated that specific functions, and accordingly utilities, of GAM515 correlate with, and may be deduced from, the identity of the target genes which GAM515 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7519] Nucleotide sequences of the GAM515 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM515 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM515 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM515 are further de-

scribed hereinbelow with reference to Table Table1.

[7520] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM515 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7521]

[7522] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 516 (GAM516) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7523] GAM516 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM516 was detected is described hereinabove with reference to Figs. 2-8.

[7524] GAM516 gene, herein designated GAM GENE, and GAM516 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7525] GAM516 gene, herein designated GAM GENE, encodes a GAM516 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM516 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM516 precursor RNA is designated SEQ ID:8218, and is provided hereinbelow with reference to the sequence listing part.

[7526] GAM516 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM516 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7527] An enzyme complex designated DICER COMPLEX, dices the GAM516 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM516 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM516 RNA is designated SEQ ID:8219, and is provided hereinbelow with reference to the sequence listing part.

[7528] GAM516 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM516 target RNA, herein designated GAM TARGET RNA. GAM516 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7529] GAM516 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM516 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM516 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM516 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM516 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7530] The complementary binding of GAM516 RNA, herein designated GAM RNA, to target binding sites on GAM516 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM516 target RNA, herein designated GAM TARGET RNA, into GAM516 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7531] It is appreciated that GAM516 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM516 target genes. The mRNA of each one of this plurality of GAM516 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM516 RNA, herein designated GAM RNA, and which when bound by GAM516 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM516 target proteins.

[7532] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM516 gene, herein designated GAM GENE, on one or more GAM516 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7533] It is yet further appreciated that specific functions, and accordingly utilities, of GAM516 correlate with, and may

be deduced from, the identity of the target genes which GAM516 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7534] Nucleotide sequences of the GAM516 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM516 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM516 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM516 are further described hereinbelow with reference to Table Table1.

[7535] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM516 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7536]

[7537] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 517 (GAM517) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7538] GAM517 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM517 was detected is described hereinabove with reference to Figs. 2-8.

[7539] GAM517 gene, herein designated GAM GENE, and GAM517 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7540] GAM517 gene, herein designated GAM GENE, encodes a GAM517 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM517 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM517 precursor RNA is designated SEQ ID:8236, and is provided hereinbelow with reference to the sequence listing part.

[7541] GAM517 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM517 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7542] An enzyme complex designated DICER COMPLEX, dices the GAM517 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM517 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 63%) nucleotide sequence of GAM517 RNA is designated SEQ ID:8237, and is provided hereinbelow with reference to the sequence listing part.

[7543] GAM517 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM517 target RNA, herein designated GAM TARGET RNA. GAM517 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7544] GAM517 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM517 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM517 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM517 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM517 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7545] The complementary binding of GAM517 RNA, herein designated GAM RNA, to target binding sites on GAM517 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM517 target RNA, herein designated GAM TARGET RNA, into GAM517 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7546] It is appreciated that GAM517 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM517 target genes. The mRNA of each one of this plurality of GAM517 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM517 RNA, herein designated GAM RNA, and which when bound by GAM517 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM517 target proteins.

[7547] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM517 gene, herein designated GAM GENE, on one or more GAM517 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7548] It is yet further appreciated that specific functions, and accordingly utilities, of GAM517 correlate with, and may be deduced from, the identity of the target genes which GAM517 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7549] Nucleotide sequences of the GAM517 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM517 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM517 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM517 are further described hereinbelow with reference to Table Table1.

[7550] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM517 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7551]

[7552] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 518 (GAM518) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7553] GAM518 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM518 was detected is described hereinabove with reference to Figs. 2-8.

[7554] GAM518 gene, herein designated GAM GENE, and GAM518 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7555] GAM518 gene, herein designated GAM GENE, encodes a GAM518 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM518 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM518 precursor RNA is desig-

nated SEQ ID:8254, and is provided hereinbelow with reference to the sequence listing part.

[7556] GAM518 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM518 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7557] An enzyme complex designated DICER COMPLEX, dices the GAM518 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM518 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 75%) nucleotide sequence of GAM518 RNA is designated SEQ ID:8255, and is provided hereinbelow with reference to the sequence listing part.

[7558] GAM518 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM518 target RNA, herein designated GAM TARGET RNA. GAM518 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7559] GAM518 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM518 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM518 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM518 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM518

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7560] The complementary binding of GAM518 RNA, herein designated GAM RNA, to target binding sites on GAM518 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM518 target RNA, herein designated GAM TARGET RNA, into GAM518 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7561] It is appreciated that GAM518 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM518 target genes. The mRNA of each one of this plurality of GAM518 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM518 RNA, herein designated GAM RNA, and which when bound by GAM518 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM518 target proteins.

[7562] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM518 gene, herein designated GAM GENE, on one or more GAM518 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7563] It is yet further appreciated that specific functions, and accordingly utilities, of GAM518 correlate with, and may be deduced from, the identity of the target genes which GAM518 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7564] Nucleotide sequences of the GAM518 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM518 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM518 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM518 are further described hereinbelow with reference to Table Table1.

[7565] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM518 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7566]

[7567] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 519 (GAM519) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7568] GAM519 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM519 was detected is described hereinabove with reference to Figs. 2-8.

[7569] GAM519 gene, herein designated GAM GENE, and

GAM519 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7570] GAM519 gene, herein designated GAM GENE, encodes a GAM519 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM519 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM519 precursor RNA is designated SEQ ID:8272, and is provided hereinbelow with reference to the sequence listing part.

[7571] GAM519 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM519 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7572] An enzyme complex designated DICER COMPLEX, dices the GAM519 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM519 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 57%) nucleotide sequence of GAM519 RNA is designated SEQ ID:8273, and is provided hereinbelow with reference to the sequence listing part.

[7573] GAM519 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM519 target RNA, herein designated GAM TARGET RNA. GAM519 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7574] GAM519 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM519 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM519 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM519 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM519 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7575] The complementary binding of GAM519 RNA, herein designated GAM RNA, to target binding sites on GAM519 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM519 target RNA, herein designated GAM TARGET RNA, into GAM519 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7576] It is appreciated that GAM519 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM519 target genes. The mRNA of each one of this plurality of GAM519 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM519 RNA, herein designated GAM RNA, and which when bound by GAM519 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM519 target proteins.

[7577] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM519 gene, herein designated GAM GENE, on one or more GAM519 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7578] It is yet further appreciated that specific functions, and accordingly utilities, of GAM519 correlate with, and may be deduced from, the identity of the target genes which GAM519 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7579] Nucleotide sequences of the GAM519 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM519 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM519 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM519 are further described hereinbelow with reference to Table Table1.

[7580] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM519 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7581]

[7582] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 520 (GAM520) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7583] GAM520 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM520 was detected is described hereinabove with reference to Figs. 2-8.

[7584] GAM520 gene, herein designated GAM GENE, and GAM520 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7585] GAM520 gene, herein designated GAM GENE, encodes a GAM520 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM520 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM520 precursor RNA is designated SEQ ID:8283, and is provided hereinbelow with reference to the sequence listing part.

[7586] GAM520 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM520 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7587] An enzyme complex designated DICER COMPLEX, dices the GAM520 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM520 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 29%) nucleotide sequence of GAM520 RNA is designated SEQ ID:8284, and is provided hereinbelow with reference to the sequence listing part.

[7588] GAM520 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM520 target RNA, herein designated GAM TARGET RNA. GAM520 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7589] GAM520 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM520 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM520 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM520 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM520 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7590] The complementary binding of GAM520 RNA, herein designated GAM RNA, to target binding sites on GAM520 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM520 target RNA, herein designated GAM TARGET RNA, into GAM520 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7591] It is appreciated that GAM520 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM520 target genes. The mRNA of each one of this plurality of GAM520 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM520 RNA, herein designated GAM RNA, and which when bound by GAM520 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM520 target proteins.

[7592] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM520 gene, herein designated GAM GENE, on one or more GAM520 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7593] It is yet further appreciated that specific functions, and accordingly utilities, of GAM520 correlate with, and may be deduced from, the identity of the target genes which GAM520 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7594] Nucleotide sequences of the GAM520 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM520 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM520 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM520 are further described hereinbelow with reference to Table Table1.

[7595] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM520 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7596]

[7597] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 521 (GAM521) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7598] GAM521 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM521 was detected is described hereinabove with reference to Figs. 2-8.

[7599] GAM521 gene, herein designated GAM GENE, and GAM521 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7600] GAM521 gene, herein designated GAM GENE, encodes a GAM521 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM521 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM521 precursor RNA is designated SEQ ID:8300, and is provided hereinbelow with reference to the sequence listing part.

[7601] GAM521 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM521 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7602] An enzyme complex designated DICER COMPLEX, dices the GAM521 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM521 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM521 RNA is designated SEQ ID:8301, and is provided hereinbelow with reference to the sequence listing part.

[7603] GAM521 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM521 target RNA, herein designated GAM TARGET RNA. GAM521 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7604] GAM521 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM521 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM521 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM521 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM521 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7605] The complementary binding of GAM521 RNA, herein designated GAM RNA, to target binding sites on GAM521 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM521 target RNA, herein designated GAM TARGET RNA, into GAM521 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7606] It is appreciated that GAM521 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM521 target genes. The mRNA of each one of this plurality of GAM521 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM521 RNA,

herein designated GAM RNA, and which when bound by GAM521 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM521 target proteins.

[7607] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM521 gene, herein designated GAM GENE, on one or more GAM521 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7608] It is yet further appreciated that specific functions, and accordingly utilities, of GAM521 correlate with, and may be deduced from, the identity of the target genes which

GAM521 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7609] Nucleotide sequences of the GAM521 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM521 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM521 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM521 are further described hereinbelow with reference to Table Table1.

[7610] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM521 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7611]

[7612] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 522 (GAM522) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7613] GAM522 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM522 was detected is described hereinabove with reference to Figs. 2-8.

[7614] GAM522 gene, herein designated GAM GENE, and GAM522 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7615] GAM522 gene, herein designated GAM GENE, encodes a GAM522 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM522 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM522 precursor RNA is designated SEQ ID:8319, and is provided hereinbelow with reference to the sequence listing part.

[7616] GAM522 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM522 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[7617] An enzyme complex designated DICER COMPLEX, dices the GAM522 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM522 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 50%) nucleotide sequence of GAM522 RNA is designated SEQ ID:8320, and is provided hereinbelow with reference to the sequence listing part.

[7618] GAM522 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM522 target RNA, herein designated GAM TARGET RNA.
GAM522 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7619] GAM522 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM522 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM522 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM522 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM522 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7620] The complementary binding of GAM522 RNA, herein designated GAM RNA, to target binding sites on GAM522 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM522 target RNA, herein desig-

nated GAM TARGET RNA, into GAM522 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7621] It is appreciated that GAM522 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM522 target genes. The mRNA of each one of this plurality of GAM522 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM522 RNA, herein designated GAM RNA, and which when bound by GAM522 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM522 target proteins.

[7622] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM522 gene, herein designated GAM GENE, on one or more GAM522 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7623] It is yet further appreciated that specific functions, and accordingly utilities, of GAM522 correlate with, and may be deduced from, the identity of the target genes which GAM522 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7624] Nucleotide sequences of the GAM522 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM522 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM522 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM522 are further described hereinbelow with reference to Table Table1.

[7625] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM522 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[7626]

[7627] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 523 (GAM523) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7628] GAM523 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM523 was detected is described hereinabove with reference to Figs. 2-8.

[7629] GAM523 gene, herein designated GAM GENE, and GAM523 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7630] GAM523 gene, herein designated GAM GENE, encodes a GAM523 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM523 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM523 precursor RNA is designated SEQ ID:8335, and is provided hereinbelow with ref-

erence to the sequence listing part.

[7631] GAM523 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM523 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7632] An enzyme complex designated DICER COMPLEX, dices the GAM523 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM523 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 66%) nucleotide sequence of GAM523 RNA is designated SEQ ID:8336, and is provided hereinbelow with reference to the sequence listing part.

[7633] GAM523 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM523 target RNA, herein designated GAM TARGET RNA.

GAM523 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7634] GAM523 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM523 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM523 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM523 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM523 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7635] The complementary binding of GAM523 RNA, herein designated GAM RNA, to target binding sites on GAM523 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM523 target RNA, herein designated GAM TARGET RNA, into GAM523 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7636] It is appreciated that GAM523 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM523 target genes. The mRNA of each one of this plurality of GAM523 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM523 RNA, herein designated GAM RNA, and which when bound by GAM523 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM523 target proteins.

[7637] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM523 gene, herein designated GAM GENE, on one or more GAM523 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7638] It is yet further appreciated that specific functions, and accordingly utilities, of GAM523 correlate with, and may be deduced from, the identity of the target genes which GAM523 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7639] Nucleotide sequences of the GAM523 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM523 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM523 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM523 are further described hereinbelow with reference to Table Table1.

[7640] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM523 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7641]

[7642] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 524 (GAM524) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7643] GAM524 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM524 was detected is described hereinabove with reference to Figs. 2-8.

[7644] GAM524 gene, herein designated GAM GENE, and GAM524 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[7645] GAM524 gene, herein designated GAM GENE, encodes a GAM524 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM524 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM524 precursor RNA is designated SEQ ID:8344, and is provided hereinbelow with reference to the sequence listing part.

[7646] GAM524 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM524 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7647] An enzyme complex designated DICER COMPLEX, dices the GAM524 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM524 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 65%) nucleotide sequence of GAM524 RNA is designated SEQ ID:8345, and is provided hereinbelow with reference to the sequence listing part.

[7648] GAM524 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM524 target RNA, herein designated GAM TARGET RNA. GAM524 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7649] GAM524 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM524 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM524 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM524 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM524 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7650] The complementary binding of GAM524 RNA, herein designated GAM RNA, to target binding sites on GAM524 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM524 target RNA, herein designated GAM TARGET RNA, into GAM524 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7651] It is appreciated that GAM524 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM524 target genes. The mRNA of each one of this plurality of GAM524 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM524 RNA, herein designated GAM RNA, and which when bound by GAM524 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM524 target proteins.

[7652] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM524 gene, herein designated GAM GENE, on one or more GAM524 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[7653] It is yet further appreciated that specific functions, and accordingly utilities, of GAM524 correlate with, and may be deduced from, the identity of the target genes which GAM524 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7654] Nucleotide sequences of the GAM524 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM524 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM524 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM524 are further described hereinbelow with reference to Table Table1.

[7655] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM524 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7656]

[7657] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

525 (GAM525) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7658] GAM525 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM525 was detected is described hereinabove with reference to Figs. 2-8.

[7659] GAM525 gene, herein designated GAM GENE, and GAM525 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7660] GAM525 gene, herein designated GAM GENE, encodes a GAM525 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM525 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM525 precursor RNA is designated SEQ ID:8355, and is provided hereinbelow with reference to the sequence listing part.

[7661] GAM525 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM525 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7662] An enzyme complex designated DICER COMPLEX, dices the GAM525 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM525 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM525 RNA is designated SEQ ID:8356, and is provided hereinbelow with reference to the sequence listing part.

[7663] GAM525 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM525 target RNA, herein designated GAM TARGET RNA. GAM525 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7664] GAM525 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM525 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM525 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM525 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM525 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7665] The complementary binding of GAM525 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM525 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM525 target RNA, herein designated GAM TARGET RNA, into GAM525 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7666] It is appreciated that GAM525 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM525 target genes. The mRNA of each one of this plurality of GAM525 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM525 RNA, herein designated GAM RNA, and which when bound by GAM525 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM525 target proteins.

[7667] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM525 gene, herein designated GAM GENE, on one or more GAM525 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7668] It is yet further appreciated that specific functions, and accordingly utilities, of GAM525 correlate with, and may be deduced from, the identity of the target genes which GAM525 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7669] Nucleotide sequences of the GAM525 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM525 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM525 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM525 are further described hereinbelow with reference to Table Table1.

[7670] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM525 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7671]

[7672] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 526 (GAM526) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7673] GAM526 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM526 was detected is described hereinabove with reference to Figs. 2-8.

[7674] GAM526 gene, herein designated GAM GENE, and GAM526 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7675] GAM526 gene, herein designated GAM GENE, encodes a GAM526 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM526 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM526 precursor RNA is designated SEQ ID:8374, and is provided hereinbelow with reference to the sequence listing part.

[7676] GAM526 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM526 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7677] An enzyme complex designated DICER COMPLEX, dices the GAM526 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM526 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 61%) nucleotide sequence of GAM526 RNA is designated SEQ ID:6904, and is provided hereinbelow with reference to the sequence listing part.

[7678] GAM526 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM526 target RNA, herein designated GAM TARGET RNA. GAM526 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7679] GAM526 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM526 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM526 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM526 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM526 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7680] The complementary binding of GAM526 RNA, herein designated GAM RNA, to target binding sites on GAM526 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM526 target RNA, herein designated GAM TARGET RNA, into GAM526 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7681] It is appreciated that GAM526 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM526 target genes. The mRNA of each one of this plurality of GAM526 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM526 RNA, herein designated GAM RNA, and which when bound by

GAM526 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM526 target proteins.

[7682] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM526 gene, herein designated GAM GENE, on one or more GAM526 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7683] It is yet further appreciated that specific functions, and accordingly utilities, of GAM526 correlate with, and may be deduced from, the identity of the target genes which GAM526 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[7684] Nucleotide sequences of the GAM526 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM526 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM526 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM526 are further described hereinbelow with reference to Table Table1.

[7685] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM526 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7686]

[7687] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 527 (GAM527) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7688] GAM527 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM527 was detected is described hereinabove with reference to Figs. 2-8.

[7689] GAM527 gene, herein designated GAM GENE, and GAM527 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7690] GAM527 gene, herein designated GAM GENE, encodes a GAM527 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM527 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM527 precursor RNA is designated SEQ ID:8390, and is provided hereinbelow with reference to the sequence listing part.

[7691] GAM527 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM527 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[7692] An enzyme complex designated DICER COMPLEX, dices the GAM527 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM527 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 28%) nucleotide sequence of GAM527 RNA is designated SEQ ID:8391, and is provided hereinbelow with reference to the sequence listing part.

[7693] GAM527 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM527 target RNA, herein designated GAM TARGET RNA. GAM527 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7694] GAM527 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM527 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM527 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM527 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM527 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7695] The complementary binding of GAM527 RNA, herein designated GAM RNA, to target binding sites on GAM527 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM527 target RNA, herein designated GAM TARGET RNA, into GAM527 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7696] It is appreciated that GAM527 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM527 target genes. The mRNA of each one of this plurality of GAM527 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM527 RNA, herein designated GAM RNA, and which when bound by GAM527 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM527 target proteins.

[7697] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM527 gene, herein designated GAM GENE, on one or more GAM527 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7698] It is yet further appreciated that specific functions, and accordingly utilities, of GAM527 correlate with, and may be deduced from, the identity of the target genes which GAM527 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7699] Nucleotide sequences of the GAM527 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM527 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM527 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM527 are further described hereinbelow with reference to Table Table1.

[7700] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM527 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7701]

[7702] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 528 (GAM528) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7703] GAM528 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM528 was detected is described hereinabove with reference to Figs. 2-8.

[7704] GAM528 gene, herein designated GAM GENE, and GAM528 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7705] GAM528 gene, herein designated GAM GENE, encodes a GAM528 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM528 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM528 precursor RNA is designated SEQ ID:8394, and is provided hereinbelow with reference to the sequence listing part.

[7706] GAM528 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM528 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7707] An enzyme complex designated DICER COMPLEX, dices the GAM528 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM528 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 59%) nucleotide sequence of GAM528 RNA is designated SEQ ID:8395, and is provided hereinbelow with reference to the sequence listing part.

[7708] GAM528 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM528

target RNA, herein designated GAM TARGET RNA.

GAM528 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7709] GAM528 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM528 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM528 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM528 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM528 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding

sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7710] The complementary binding of GAM528 RNA, herein designated GAM RNA, to target binding sites on GAM528 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM528 target RNA, herein designated GAM TARGET RNA, into GAM528 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7711] It is appreciated that GAM528 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM528 target genes. The mRNA of each one of this plurality of GAM528 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM528 RNA, herein designated GAM RNA, and which when bound by GAM528 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM528 target proteins.

[7712] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with

specific reference to translational inhibition exerted by GAM528 gene, herein designated GAM GENE, on one or more GAM528 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7713] It is yet further appreciated that specific functions, and accordingly utilities, of GAM528 correlate with, and may be deduced from, the identity of the target genes which GAM528 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7714] Nucleotide sequences of the GAM528 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM528 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of

GAM528 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM528 are further described hereinbelow with reference to Table Table1.

[7715] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM528 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7716]

[7717] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 529 (GAM529) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7718] GAM529 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM529 was detected is described hereinabove with reference to Figs. 2-8.

[7719] GAM529 gene, herein designated GAM GENE, and GAM529 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7720] GAM529 gene, herein designated GAM GENE, encodes a GAM529 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM529 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM529 precursor RNA is designated SEQ ID:8403, and is provided hereinbelow with reference to the sequence listing part.

[7721] GAM529 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM529 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7722] An enzyme complex designated DICER COMPLEX, dices the GAM529 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM529 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA

segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 72%) nucleotide sequence of GAM529 RNA is designated SEQ ID:8404, and is provided hereinbelow with reference to the sequence listing part.

[7723] GAM529 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM529 target RNA, herein designated GAM TARGET RNA. GAM529 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7724] GAM529 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM529 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM529 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustra-

tion, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM529 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM529 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7725] The complementary binding of GAM529 RNA, herein designated GAM RNA, to target binding sites on GAM529 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM529 target RNA, herein designated GAM TARGET RNA, into GAM529 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7726] It is appreciated that GAM529 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM529 target genes. The mRNA of each one of this plu-

rality of GAM529 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM529 RNA, herein designated GAM RNA, and which when bound by GAM529 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM529 target proteins.

[7727] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM529 gene, herein designated GAM GENE, on one or more GAM529 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7728] It is yet further appreciated that specific functions, and accordingly utilities, of GAM529 correlate with, and may be deduced from, the identity of the target genes which GAM529 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7729] Nucleotide sequences of the GAM529 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM529 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM529 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM529 are further described hereinbelow with reference to Table Table1.

[7730] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM529 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7731]

[7732] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 530 (GAM530) gene, which modulates expression of re-

spective target genes thereof, the function and utility of which target genes is known in the art.

[7733] GAM530 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM530 was detected is described hereinabove with reference to Figs. 2-8.

[7734] GAM530 gene, herein designated GAM GENE, and GAM530 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7735] GAM530 gene, herein designated GAM GENE, encodes a GAM530 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM530 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM530 precursor RNA is designated SEQ ID:8432, and is provided hereinbelow with reference to the sequence listing part.

[7736] GAM530 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM530 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of

RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7737] An enzyme complex designated DICER COMPLEX, dices the GAM530 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM530 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 67%) nucleotide sequence of GAM530 RNA is designated SEQ ID:8433, and is provided hereinbelow with reference to the sequence listing part.

[7738] GAM530 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM530 target RNA, herein designated GAM TARGET RNA.
GAM530 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated

5UTR, PROTEIN CODING and 3UTR respectively.

[7739] GAM530 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM530 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM530 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM530 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM530 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7740] The complementary binding of GAM530 RNA, herein designated GAM RNA, to target binding sites on GAM530 tar-

get RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM530 target RNA, herein designated GAM TARGET RNA, into GAM530 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7741] It is appreciated that GAM530 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM530 target genes. The mRNA of each one of this plurality of GAM530 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM530 RNA, herein designated GAM RNA, and which when bound by GAM530 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM530 target proteins.

[7742] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM530 gene, herein designated GAM GENE, on one or more GAM530 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the

background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7743] It is yet further appreciated that specific functions, and accordingly utilities, of GAM530 correlate with, and may be deduced from, the identity of the target genes which GAM530 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7744] Nucleotide sequences of the GAM530 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM530 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM530 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM530 are further described hereinbelow with reference to Table Table1.

[7745] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of

Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM530 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7746]

[7747] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 531 (GAM531) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7748] GAM531 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM531 was detected is described hereinabove with reference to Figs. 2-8.

[7749] GAM531 gene, herein designated GAM GENE, and GAM531 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7750] GAM531 gene, herein designated GAM GENE, encodes a GAM531 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM531 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A

nucleotide sequence identical or highly similar to the nucleotide sequence of GAM531 precursor RNA is designated SEQ ID:8440, and is provided hereinbelow with reference to the sequence listing part.

[7751] GAM531 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM531 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7752] An enzyme complex designated DICER COMPLEX, dices the GAM531 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM531 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 41%) nucleotide sequence of

GAM531 RNA is designated SEQ ID:8441, and is provided hereinbelow with reference to the sequence listing part.

[7753] GAM531 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM531 target RNA, herein designated GAM TARGET RNA. GAM531 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7754] GAM531 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM531 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM531 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM531 RNA, herein

designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM531 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7755] The complementary binding of GAM531 RNA, herein designated GAM RNA, to target binding sites on GAM531 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM531 target RNA, herein designated GAM TARGET RNA, into GAM531 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7756] It is appreciated that GAM531 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM531 target genes. The mRNA of each one of this plurality of GAM531 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM531 RNA, herein designated GAM RNA, and which when bound by GAM531 RNA, herein designated GAM RNA, causes inhibi-

tion of translation of respective one or more GAM531 target proteins.

[7757] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM531 gene, herein designated GAM GENE, on one or more GAM531 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7758] It is yet further appreciated that specific functions, and accordingly utilities, of GAM531 correlate with, and may be deduced from, the identity of the target genes which GAM531 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7759] Nucleotide sequences of the GAM531 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM531 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM531 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM531 are further described hereinbelow with reference to Table Table1.

[7760] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM531 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7761]

[7762] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 532 (GAM532) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7763] GAM532 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM532 was detected is described hereinabove

with reference to Figs. 2-8.

[7764] GAM532 gene, herein designated GAM GENE, and GAM532 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7765] GAM532 gene, herein designated GAM GENE, encodes a GAM532 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM532 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM532 precursor RNA is designated SEQ ID:8449, and is provided hereinbelow with reference to the sequence listing part.

[7766] GAM532 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM532 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7767] An enzyme complex designated DICER COMPLEX, dices the GAM532 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM532 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 42%) nucleotide sequence of GAM532 RNA is designated SEQ ID:8441, and is provided hereinbelow with reference to the sequence listing part.

[7768] GAM532 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM532 target RNA, herein designated GAM TARGET RNA. GAM532 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7769] GAM532 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM532 target RNA, herein designated GAM TARGET RNA. This complementary binding is

due to the fact that the nucleotide sequence of GAM532 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM532 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM532 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7770] The complementary binding of GAM532 RNA, herein designated GAM RNA, to target binding sites on GAM532 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM532 target RNA, herein designated GAM TARGET RNA, into GAM532 target protein, herein designated GAM TARGET PROTEIN. GAM target

protein is therefore outlined by a broken line.

[7771] It is appreciated that GAM532 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM532 target genes. The mRNA of each one of this plurality of GAM532 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM532 RNA, herein designated GAM RNA, and which when bound by GAM532 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM532 target proteins.

[7772] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM532 gene, herein designated GAM GENE, on one or more GAM532 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other

genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7773] It is yet further appreciated that specific functions, and accordingly utilities, of GAM532 correlate with, and may be deduced from, the identity of the target genes which GAM532 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7774] Nucleotide sequences of the GAM532 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM532 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM532 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM532 are further described hereinbelow with reference to Table Table1.

[7775] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM532 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7776]

[7777] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 533 (GAM533) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7778] GAM533 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM533 was detected is described hereinabove with reference to Figs. 2-8.

[7779] GAM533 gene, herein designated GAM GENE, and GAM533 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7780] GAM533 gene, herein designated GAM GENE, encodes a GAM533 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM533 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM533 precursor RNA is designated SEQ ID:8469, and is provided hereinbelow with reference to the sequence listing part.

[7781] GAM533 precursor RNA, herein designated GAM PRECUR-

SOR RNA, folds onto itself, forming GAM533 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7782] An enzyme complex designated DICER COMPLEX, dices the GAM533 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM533 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 58%) nucleotide sequence of GAM533 RNA is designated SEQ ID:8470, and is provided hereinbelow with reference to the sequence listing part.

[7783] GAM533 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM533 target RNA, herein designated GAM TARGET RNA.

GAM533 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7784] GAM533 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM533 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM533 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM533 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM533 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only

these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7785] The complementary binding of GAM533 RNA, herein designated GAM RNA, to target binding sites on GAM533 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM533 target RNA, herein designated GAM TARGET RNA, into GAM533 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7786] It is appreciated that GAM533 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM533 target genes. The mRNA of each one of this plurality of GAM533 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM533 RNA, herein designated GAM RNA, and which when bound by GAM533 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM533 target proteins.

[7787] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by

GAM533 gene, herein designated GAM GENE, on one or more GAM533 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7788] It is yet further appreciated that specific functions, and accordingly utilities, of GAM533 correlate with, and may be deduced from, the identity of the target genes which GAM533 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7789] Nucleotide sequences of the GAM533 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM533 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM533 folded precursor RNA, herein designated GAM

FOLDED PRECURSOR RNA, of GAM533 are further described hereinbelow with reference to Table Table1.

[7790] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM533 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7791]

[7792] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 534 (GAM534) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7793] GAM534 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM534 was detected is described hereinabove with reference to Figs. 2-8.

[7794] GAM534 gene, herein designated GAM GENE, and GAM534 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7795] GAM534 gene, herein designated GAM GENE, encodes a

GAM534 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM534 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM534 precursor RNA is designated SEQ ID:8493, and is provided hereinbelow with reference to the sequence listing part.

[7796] GAM534 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM534 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7797] An enzyme complex designated DICER COMPLEX, dices the GAM534 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM534 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin struc-

tured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM534 RNA is designated SEQ ID:8494, and is provided hereinbelow with reference to the sequence listing part.

[7798] GAM534 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM534 target RNA, herein designated GAM TARGET RNA. GAM534 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7799] GAM534 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM534 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM534 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated

BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM534 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM534 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7800] The complementary binding of GAM534 RNA, herein designated GAM RNA, to target binding sites on GAM534 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM534 target RNA, herein designated GAM TARGET RNA, into GAM534 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7801] It is appreciated that GAM534 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM534 target genes. The mRNA of each one of this plurality of GAM534 target genes comprises one or more tar-

get binding sites, each having a nucleotide sequence which is at least partly complementary to GAM534 RNA, herein designated GAM RNA, and which when bound by GAM534 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM534 target proteins.

[7802] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM534 gene, herein designated GAM GENE, on one or more GAM534 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7803] It is yet further appreciated that specific functions, and

accordingly utilities, of GAM534 correlate with, and may be deduced from, the identity of the target genes which GAM534 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7804] Nucleotide sequences of the GAM534 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM534 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM534 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM534 are further described hereinbelow with reference to Table Table1.

[7805] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM534 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7806]

[7807] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 535 (GAM535) gene, which modulates expression of respective target genes thereof, the function and utility of

which target genes is known in the art.

[7808] GAM535 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM535 was detected is described hereinabove with reference to Figs. 2-8.

[7809] GAM535 gene, herein designated GAM GENE, and GAM535 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7810] GAM535 gene, herein designated GAM GENE, encodes a GAM535 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM535 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM535 precursor RNA is designated SEQ ID:8508, and is provided hereinbelow with reference to the sequence listing part.

[7811] GAM535 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM535 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that

the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7812] An enzyme complex designated DICER COMPLEX, dices the GAM535 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM535 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 64%) nucleotide sequence of GAM535 RNA is designated SEQ ID:8509, and is provided hereinbelow with reference to the sequence listing part.

[7813] GAM535 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM535 target RNA, herein designated GAM TARGET RNA. GAM535 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7814] GAM535 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM535 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM535 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM535 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM535 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7815] The complementary binding of GAM535 RNA, herein designated GAM RNA, to target binding sites on GAM535 target RNA, herein designated GAM TARGET RNA, such as

BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM535 target RNA, herein designated GAM TARGET RNA, into GAM535 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7816] It is appreciated that GAM535 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM535 target genes. The mRNA of each one of this plurality of GAM535 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM535 RNA, herein designated GAM RNA, and which when bound by GAM535 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM535 target proteins.

[7817] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM535 gene, herein designated GAM GENE, on one or more GAM535 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary

binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7818] It is yet further appreciated that specific functions, and accordingly utilities, of GAM535 correlate with, and may be deduced from, the identity of the target genes which GAM535 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7819] Nucleotide sequences of the GAM535 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM535 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM535 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM535 are further described hereinbelow with reference to Table Table1.

[7820] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the

complementarity of each of these target binding sites to GAM535 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7821]

[7822] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 536 (GAM536) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7823] GAM536 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM536 was detected is described hereinabove with reference to Figs. 2-8.

[7824] GAM536 gene, herein designated GAM GENE, and GAM536 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7825] GAM536 gene, herein designated GAM GENE, encodes a GAM536 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM536 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nu-

cleotide sequence of GAM536 precursor RNA is designated SEQ ID:8519, and is provided hereinbelow with reference to the sequence listing part.

[7826] GAM536 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM536 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7827] An enzyme complex designated DICER COMPLEX, dices the GAM536 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM536 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 52%) nucleotide sequence of GAM536 RNA is designated SEQ ID:8520, and is provided

hereinbelow with reference to the sequence listing part.

[7828] GAM536 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM536 target RNA, herein designated GAM TARGET RNA.

GAM536 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7829] GAM536 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM536 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM536 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM536 RNA, herein designated GAM RNA, may have a different number of tar-

get binding sites in untranslated regions of a GAM536 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7830] The complementary binding of GAM536 RNA, herein designated GAM RNA, to target binding sites on GAM536 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM536 target RNA, herein designated GAM TARGET RNA, into GAM536 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7831] It is appreciated that GAM536 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM536 target genes. The mRNA of each one of this plurality of GAM536 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM536 RNA, herein designated GAM RNA, and which when bound by GAM536 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM536 tar-

get proteins.

[7832] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM536 gene, herein designated GAM GENE, on one or more GAM536 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7833] It is yet further appreciated that specific functions, and accordingly utilities, of GAM536 correlate with, and may be deduced from, the identity of the target genes which GAM536 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7834] Nucleotide sequences of the GAM536 precursor RNA,

herein designated GAM PRECURSOR RNA, and of the diced GAM536 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM536 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM536 are further described hereinbelow with reference to Table Table1.

[7835] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM536 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7836]

[7837] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 537 (GAM537) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7838] GAM537 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM537 was detected is described hereinabove with reference to Figs. 2-8.

[7839] GAM537 gene, herein designated GAM GENE, and GAM537 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7840] GAM537 gene, herein designated GAM GENE, encodes a GAM537 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM537 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM537 precursor RNA is designated SEQ ID:8528, and is provided hereinbelow with reference to the sequence listing part.

[7841] GAM537 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM537 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7842] An enzyme complex designated DICER COMPLEX, dices

the GAM537 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM537 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 39%) nucleotide sequence of GAM537 RNA is designated SEQ ID:8529, and is provided hereinbelow with reference to the sequence listing part.

[7843] GAM537 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM537 target RNA, herein designated GAM TARGET RNA. GAM537 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7844] GAM537 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM537 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM537

RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM537 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM537 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7845] The complementary binding of GAM537 RNA, herein designated GAM RNA, to target binding sites on GAM537 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM537 target RNA, herein designated GAM TARGET RNA, into GAM537 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7846] It is appreciated that GAM537 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM537 target genes. The mRNA of each one of this plurality of GAM537 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM537 RNA, herein designated GAM RNA, and which when bound by GAM537 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM537 target proteins.

[7847] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM537 gene, herein designated GAM GENE, on one or more GAM537 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific com-

plementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7848] It is yet further appreciated that specific functions, and accordingly utilities, of GAM537 correlate with, and may be deduced from, the identity of the target genes which GAM537 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7849] Nucleotide sequences of the GAM537 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM537 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM537 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM537 are further described hereinbelow with reference to Table Table1.

[7850] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM537 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7851]

[7852] Fig. 8 further provides a conceptual description of another

novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 538 (GAM538) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7853] GAM538 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM538 was detected is described hereinabove with reference to Figs. 2-8.

[7854] GAM538 gene, herein designated GAM GENE, and GAM538 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7855] GAM538 gene, herein designated GAM GENE, encodes a GAM538 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM538 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM538 precursor RNA is designated SEQ ID:8549, and is provided hereinbelow with reference to the sequence listing part.

[7856] GAM538 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM538 folded pre-

cursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7857] An enzyme complex designated DICER COMPLEX, dices the GAM538 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM538 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 28%) nucleotide sequence of GAM538 RNA is designated SEQ ID:8550, and is provided hereinbelow with reference to the sequence listing part.

[7858] GAM538 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM538 target RNA, herein designated GAM TARGET RNA. GAM538 target RNA, herein designated GAM TARGET

RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7859] GAM538 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM538 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM538 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM538 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM538 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR re-

gion, the 5UTR region, or in both 3UTR and 5UTR regions.

[7860] The complementary binding of GAM538 RNA, herein designated GAM RNA, to target binding sites on GAM538 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM538 target RNA, herein designated GAM TARGET RNA, into GAM538 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7861] It is appreciated that GAM538 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM538 target genes. The mRNA of each one of this plurality of GAM538 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM538 RNA, herein designated GAM RNA, and which when bound by GAM538 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM538 target proteins.

[7862] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM538 gene, herein designated GAM GENE, on one or

more GAM538 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7863] It is yet further appreciated that specific functions, and accordingly utilities, of GAM538 correlate with, and may be deduced from, the identity of the target genes which GAM538 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7864] Nucleotide sequences of the GAM538 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM538 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM538 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM538 are further de-

scribed hereinbelow with reference to Table Table1.

[7865] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM538 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7866]

[7867] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 539 (GAM539) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7868] GAM539 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM539 was detected is described hereinabove with reference to Figs. 2-8.

[7869] GAM539 gene, herein designated GAM GENE, and GAM539 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7870] GAM539 gene, herein designated GAM GENE, encodes a GAM539 precursor RNA, herein designated GAM PRECUR-

SOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM539 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM539 precursor RNA is designated SEQ ID:8564, and is provided hereinbelow with reference to the sequence listing part.

[7871] GAM539 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM539 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7872] An enzyme complex designated DICER COMPLEX, dices the GAM539 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM539 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA seg-

ment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 60%) nucleotide sequence of GAM539 RNA is designated SEQ ID:8565, and is provided hereinbelow with reference to the sequence listing part.

[7873] GAM539 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM539 target RNA, herein designated GAM TARGET RNA. GAM539 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7874] GAM539 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM539 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM539 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III re-

spectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM539 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM539 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7875] The complementary binding of GAM539 RNA, herein designated GAM RNA, to target binding sites on GAM539 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM539 target RNA, herein designated GAM TARGET RNA, into GAM539 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7876] It is appreciated that GAM539 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM539 target genes. The mRNA of each one of this plurality of GAM539 target genes comprises one or more target binding sites, each having a nucleotide sequence

which is at least partly complementary to GAM539 RNA, herein designated GAM RNA, and which when bound by GAM539 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM539 target proteins.

[7877] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM539 gene, herein designated GAM GENE, on one or more GAM539 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7878] It is yet further appreciated that specific functions, and accordingly utilities, of GAM539 correlate with, and may

be deduced from, the identity of the target genes which GAM539 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7879] Nucleotide sequences of the GAM539 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM539 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM539 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM539 are further described hereinbelow with reference to Table Table1.

[7880] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM539 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7881]

[7882] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 540 (GAM540) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7883] GAM540 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM540 was detected is described hereinabove with reference to Figs. 2-8.

[7884] GAM540 gene, herein designated GAM GENE, and GAM540 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7885] GAM540 gene, herein designated GAM GENE, encodes a GAM540 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM540 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM540 precursor RNA is designated SEQ ID:8567, and is provided hereinbelow with reference to the sequence listing part.

[7886] GAM540 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM540 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA en-

coded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7887] An enzyme complex designated DICER COMPLEX, dices the GAM540 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM540 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 54%) nucleotide sequence of GAM540 RNA is designated SEQ ID:8568, and is provided hereinbelow with reference to the sequence listing part.

[7888] GAM540 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM540 target RNA, herein designated GAM TARGET RNA. GAM540 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7889] GAM540 RNA, herein designated GAM RNA, binds com-

plementarily to one or more target binding sites located in untranslated regions of GAM540 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM540 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM540 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM540 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7890] The complementary binding of GAM540 RNA, herein designated GAM RNA, to target binding sites on GAM540 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, in-

hibits translation of GAM540 target RNA, herein designated GAM TARGET RNA, into GAM540 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7891] It is appreciated that GAM540 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM540 target genes. The mRNA of each one of this plurality of GAM540 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM540 RNA, herein designated GAM RNA, and which when bound by GAM540 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM540 target proteins.

[7892] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM540 gene, herein designated GAM GENE, on one or more GAM540 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the

known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7893] It is yet further appreciated that specific functions, and accordingly utilities, of GAM540 correlate with, and may be deduced from, the identity of the target genes which GAM540 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7894] Nucleotide sequences of the GAM540 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM540 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM540 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM540 are further described hereinbelow with reference to Table Table1.

[7895] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to

GAM540 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7896]

[7897] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 541 (GAM541) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7898] GAM541 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM541 was detected is described hereinabove with reference to Figs. 2-8.

[7899] GAM541 gene, herein designated GAM GENE, and GAM541 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7900] GAM541 gene, herein designated GAM GENE, encodes a GAM541 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM541 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM541 precursor RNA is desig-

nated SEQ ID:8573, and is provided hereinbelow with reference to the sequence listing part.

[7901] GAM541 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM541 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7902] An enzyme complex designated DICER COMPLEX, dices the GAM541 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM541 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 30%) nucleotide sequence of GAM541 RNA is designated SEQ ID:8574, and is provided hereinbelow with reference to the sequence listing part.

[7903] GAM541 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM541 target RNA, herein designated GAM TARGET RNA. GAM541 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7904] GAM541 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM541 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM541 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM541 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM541

target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7905] The complementary binding of GAM541 RNA, herein designated GAM RNA, to target binding sites on GAM541 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM541 target RNA, herein designated GAM TARGET RNA, into GAM541 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7906] It is appreciated that GAM541 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM541 target genes. The mRNA of each one of this plurality of GAM541 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM541 RNA, herein designated GAM RNA, and which when bound by GAM541 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM541 target proteins.

[7907] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM541 gene, herein designated GAM GENE, on one or more GAM541 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7908] It is yet further appreciated that specific functions, and accordingly utilities, of GAM541 correlate with, and may be deduced from, the identity of the target genes which GAM541 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7909] Nucleotide sequences of the GAM541 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced

GAM541 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM541 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM541 are further described hereinbelow with reference to Table Table1.

[7910] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM541 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7911]

[7912] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 542 (GAM542) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7913] GAM542 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM542 was detected is described hereinabove with reference to Figs. 2-8.

[7914] GAM542 gene, herein designated GAM GENE, and

GAM542 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7915] GAM542 gene, herein designated GAM GENE, encodes a GAM542 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM542 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM542 precursor RNA is designated SEQ ID:8579, and is provided hereinbelow with reference to the sequence listing part.

[7916] GAM542 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM542 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7917] An enzyme complex designated DICER COMPLEX, dices the GAM542 folded precursor RNA, herein designated

GAM FOLDED PRECURSOR RNA, into GAM542 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 62%) nucleotide sequence of GAM542 RNA is designated SEQ ID:8580, and is provided hereinbelow with reference to the sequence listing part.

[7918] GAM542 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM542 target RNA, herein designated GAM TARGET RNA. GAM542 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7919] GAM542 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM542 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM542 RNA, herein designated GAM RNA, is an accurate or a par-

tial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM542 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM542 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7920] The complementary binding of GAM542 RNA, herein designated GAM RNA, to target binding sites on GAM542 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM542 target RNA, herein designated GAM TARGET RNA, into GAM542 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7921] It is appreciated that GAM542 target gene, herein desig-

nated GAM TARGET GENE, in fact represents a plurality of GAM542 target genes. The mRNA of each one of this plurality of GAM542 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM542 RNA, herein designated GAM RNA, and which when bound by GAM542 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM542 target proteins.

[7922] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM542 gene, herein designated GAM GENE, on one or more GAM542 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have

not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7923] It is yet further appreciated that specific functions, and accordingly utilities, of GAM542 correlate with, and may be deduced from, the identity of the target genes which GAM542 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7924] Nucleotide sequences of the GAM542 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM542 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM542 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM542 are further described hereinbelow with reference to Table Table1.

[7925] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM542 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7926]

[7927] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present in-

vention, referred to here as Genomic Address Messenger 543 (GAM543) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7928] GAM543 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM543 was detected is described hereinabove with reference to Figs. 2-8.

[7929] GAM543 gene, herein designated GAM GENE, and GAM543 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7930] GAM543 gene, herein designated GAM GENE, encodes a GAM543 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM543 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM543 precursor RNA is designated SEQ ID:8608, and is provided hereinbelow with reference to the sequence listing part.

[7931] GAM543 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM543 folded precursor RNA, herein designated GAM FOLDED PRECURSOR

RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7932] An enzyme complex designated DICER COMPLEX, dices the GAM543 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM543 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM543 RNA is designated SEQ ID:8609, and is provided hereinbelow with reference to the sequence listing part.

[7933] GAM543 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM543 target RNA, herein designated GAM TARGET RNA. GAM543 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a

protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7934] GAM543 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM543 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM543 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM543 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM543 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7935] The complementary binding of GAM543 RNA, herein designated GAM RNA, to target binding sites on GAM543 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM543 target RNA, herein designated GAM TARGET RNA, into GAM543 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7936] It is appreciated that GAM543 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM543 target genes. The mRNA of each one of this plurality of GAM543 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM543 RNA, herein designated GAM RNA, and which when bound by GAM543 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM543 target proteins.

[7937] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM543 gene, herein designated GAM GENE, on one or more GAM543 target gene, herein designated GAM TAR-

GET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7938] It is yet further appreciated that specific functions, and accordingly utilities, of GAM543 correlate with, and may be deduced from, the identity of the target genes which GAM543 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7939] Nucleotide sequences of the GAM543 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM543 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM543 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM543 are further described hereinbelow with reference to Table Table1.

[7940] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM543 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7941]

[7942] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 544 (GAM544) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7943] GAM544 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM544 was detected is described hereinabove with reference to Figs. 2-8.

[7944] GAM544 gene, herein designated GAM GENE, and GAM544 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7945] GAM544 gene, herein designated GAM GENE, encodes a GAM544 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most

ordinary genes, GAM544 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM544 precursor RNA is designated SEQ ID:8621, and is provided hereinbelow with reference to the sequence listing part.

[7946] GAM544 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM544 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7947] An enzyme complex designated DICER COMPLEX, dices the GAM544 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM544 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an

enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM544 RNA is designated SEQ ID:8622, and is provided hereinbelow with reference to the sequence listing part.

[7948] GAM544 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM544 target RNA, herein designated GAM TARGET RNA. GAM544 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7949] GAM544 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM544 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM544 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target

binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM544 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM544 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7950] The complementary binding of GAM544 RNA, herein designated GAM RNA, to target binding sites on GAM544 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM544 target RNA, herein designated GAM TARGET RNA, into GAM544 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7951] It is appreciated that GAM544 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM544 target genes. The mRNA of each one of this plurality of GAM544 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM544 RNA,

herein designated GAM RNA, and which when bound by GAM544 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM544 target proteins.

[7952] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM544 gene, herein designated GAM GENE, on one or more GAM544 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7953] It is yet further appreciated that specific functions, and accordingly utilities, of GAM544 correlate with, and may be deduced from, the identity of the target genes which

GAM544 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7954] Nucleotide sequences of the GAM544 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM544 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM544 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM544 are further described hereinbelow with reference to Table Table1.

[7955] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM544 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7956]

[7957] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 545 (GAM545) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7958] GAM545 is a novel bioinformatically detected regulatory,

non protein coding, micro RNA (miRNA) gene. The method by which GAM545 was detected is described hereinabove with reference to Figs. 2-8.

[7959] GAM545 gene, herein designated GAM GENE, and GAM545 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7960] GAM545 gene, herein designated GAM GENE, encodes a GAM545 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM545 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM545 precursor RNA is designated SEQ ID:8652, and is provided hereinbelow with reference to the sequence listing part.

[7961] GAM545 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM545 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-

reversed sequence of the nucleotide sequence of the second half thereof.

[7962] An enzyme complex designated DICER COMPLEX, dices the GAM545 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM545 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM545 RNA is designated SEQ ID:8622, and is provided hereinbelow with reference to the sequence listing part.

[7963] GAM545 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM545 target RNA, herein designated GAM TARGET RNA.
GAM545 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7964] GAM545 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in

untranslated regions of GAM545 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM545 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM545 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM545 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7965] The complementary binding of GAM545 RNA, herein designated GAM RNA, to target binding sites on GAM545 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM545 target RNA, herein desig-

nated GAM TARGET RNA, into GAM545 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7966] It is appreciated that GAM545 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM545 target genes. The mRNA of each one of this plurality of GAM545 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM545 RNA, herein designated GAM RNA, and which when bound by GAM545 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM545 target proteins.

[7967] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM545 gene, herein designated GAM GENE, on one or more GAM545 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other

recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7968] It is yet further appreciated that specific functions, and accordingly utilities, of GAM545 correlate with, and may be deduced from, the identity of the target genes which GAM545 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7969] Nucleotide sequences of the GAM545 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM545 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM545 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM545 are further described hereinbelow with reference to Table Table1.

[7970] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM545 RNA, herein designated GAM RNA, are described

hereinbelow with reference to Table Table2.

[7971]

[7972] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 546 (GAM546) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7973] GAM546 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM546 was detected is described hereinabove with reference to Figs. 2-8.

[7974] GAM546 gene, herein designated GAM GENE, and GAM546 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[7975] GAM546 gene, herein designated GAM GENE, encodes a GAM546 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM546 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM546 precursor RNA is designated SEQ ID:8687, and is provided hereinbelow with ref-

erence to the sequence listing part.

[7976] GAM546 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM546 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7977] An enzyme complex designated DICER COMPLEX, dices the GAM546 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM546 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 71%) nucleotide sequence of GAM546 RNA is designated SEQ ID:8609, and is provided hereinbelow with reference to the sequence listing part.

[7978] GAM546 target gene, herein designated GAM TARGET

GENE, encodes a corresponding messenger RNA, GAM546 target RNA, herein designated GAM TARGET RNA.

GAM546 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7979] GAM546 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM546 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM546 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM546 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM546 target RNA, herein designated GAM TARGET RNA. It is fur-

ther appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7980] The complementary binding of GAM546 RNA, herein designated GAM RNA, to target binding sites on GAM546 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM546 target RNA, herein designated GAM TARGET RNA, into GAM546 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7981] It is appreciated that GAM546 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM546 target genes. The mRNA of each one of this plurality of GAM546 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM546 RNA, herein designated GAM RNA, and which when bound by GAM546 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM546 target proteins.

[7982] It is further appreciated by one skilled in the art that the

mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM546 gene, herein designated GAM GENE, on one or more GAM546 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[7983] It is yet further appreciated that specific functions, and accordingly utilities, of GAM546 correlate with, and may be deduced from, the identity of the target genes which GAM546 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7984] Nucleotide sequences of the GAM546 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM546 RNA, herein designated GAM RNA, and a

schematic representation of the secondary folding of GAM546 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM546 are further described hereinbelow with reference to Table Table1.

[7985] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM546 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[7986]

[7987] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 547 (GAM547) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[7988] GAM547 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM547 was detected is described hereinabove with reference to Figs. 2-8.

[7989] GAM547 gene, herein designated GAM GENE, and GAM547 target gene, herein designated GAM TARGET

GENE, are human genes contained in the human genome.

[7990] GAM547 gene, herein designated GAM GENE, encodes a GAM547 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM547 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM547 precursor RNA is designated SEQ ID:8715, and is provided hereinbelow with reference to the sequence listing part.

[7991] GAM547 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM547 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[7992] An enzyme complex designated DICER COMPLEX, dices the GAM547 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM547 RNA, herein

designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 56%) nucleotide sequence of GAM547 RNA is designated SEQ ID:8716, and is provided hereinbelow with reference to the sequence listing part.

[7993] GAM547 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM547 target RNA, herein designated GAM TARGET RNA. GAM547 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[7994] GAM547 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM547 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM547 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide se-

quence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM547 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM547 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[7995] The complementary binding of GAM547 RNA, herein designated GAM RNA, to target binding sites on GAM547 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM547 target RNA, herein designated GAM TARGET RNA, into GAM547 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[7996] It is appreciated that GAM547 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of

GAM547 target genes. The mRNA of each one of this plurality of GAM547 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM547 RNA, herein designated GAM RNA, and which when bound by GAM547 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM547 target proteins.

[7997] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM547 gene, herein designated GAM GENE, on one or more GAM547 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a

tiny RNA world, Science 294,779 (2001)).

[7998] It is yet further appreciated that specific functions, and accordingly utilities, of GAM547 correlate with, and may be deduced from, the identity of the target genes which GAM547 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[7999] Nucleotide sequences of the GAM547 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM547 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM547 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM547 are further described hereinbelow with reference to Table Table1.

[8000] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM547 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[8001]

[8002] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger

548 (GAM548) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[8003] GAM548 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM548 was detected is described hereinabove with reference to Figs. 2-8.

[8004] GAM548 gene, herein designated GAM GENE, and GAM548 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[8005] GAM548 gene, herein designated GAM GENE, encodes a GAM548 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM548 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM548 precursor RNA is designated SEQ ID:8724, and is provided hereinbelow with reference to the sequence listing part.

[8006] GAM548 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM548 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is

well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[8007] An enzyme complex designated DICER COMPLEX, dices the GAM548 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM548 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 53%) nucleotide sequence of GAM548 RNA is designated SEQ ID:8725, and is provided hereinbelow with reference to the sequence listing part.

[8008] GAM548 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM548 target RNA, herein designated GAM TARGET RNA. GAM548 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein

coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[8009] GAM548 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM548 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM548 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM548 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM548 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[8010] The complementary binding of GAM548 RNA, herein des-

ignated GAM RNA, to target binding sites on GAM548 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM548 target RNA, herein designated GAM TARGET RNA, into GAM548 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[8011] It is appreciated that GAM548 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM548 target genes. The mRNA of each one of this plurality of GAM548 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM548 RNA, herein designated GAM RNA, and which when bound by GAM548 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM548 target proteins.

[8012] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM548 gene, herein designated GAM GENE, on one or more GAM548 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA

genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[8013] It is yet further appreciated that specific functions, and accordingly utilities, of GAM548 correlate with, and may be deduced from, the identity of the target genes which GAM548 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[8014] Nucleotide sequences of the GAM548 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM548 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM548 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM548 are further described hereinbelow with reference to Table Table1.

[8015] Nucleotide sequences of target binding sites, such as

BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM548 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[8016]

[8017] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 549 (GAM549) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[8018] GAM549 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method by which GAM549 was detected is described hereinabove with reference to Figs. 2-8.

[8019] GAM549 gene, herein designated GAM GENE, and GAM549 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[8020] GAM549 gene, herein designated GAM GENE, encodes a GAM549 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM549 precursor RNA, herein desig-

nated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM549 precursor RNA is designated SEQ ID:8728, and is provided hereinbelow with reference to the sequence listing part.

[8021] GAM549 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM549 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the second half thereof.

[8022] An enzyme complex designated DICER COMPLEX, dices the GAM549 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM549 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary pro-

teins. A probable (over 49%) nucleotide sequence of GAM549 RNA is designated SEQ ID:8729, and is provided hereinbelow with reference to the sequence listing part.

[8023] GAM549 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM549 target RNA, herein designated GAM TARGET RNA. GAM549 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[8024] GAM549 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM549 target RNA, herein designated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM549 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration

only, and is not meant to be limiting GAM549 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM549 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[8025] The complementary binding of GAM549 RNA, herein designated GAM RNA, to target binding sites on GAM549 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM549 target RNA, herein designated GAM TARGET RNA, into GAM549 target protein, herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[8026] It is appreciated that GAM549 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM549 target genes. The mRNA of each one of this plurality of GAM549 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM549 RNA, herein designated GAM RNA, and which when bound by

GAM549 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM549 target proteins.

[8027] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM549 gene, herein designated GAM GENE, on one or more GAM549 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[8028] It is yet further appreciated that specific functions, and accordingly utilities, of GAM549 correlate with, and may be deduced from, the identity of the target genes which GAM549 binds and inhibits, and the function of these tar-

get genes, as elaborated hereinbelow.

[8029] Nucleotide sequences of the GAM549 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM549 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM549 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM549 are further described hereinbelow with reference to Table Table1.

[8030] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM549 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[8031]

[8032] Fig. 8 further provides a conceptual description of another novel bioinformatically detected gene of the present invention, referred to here as Genomic Address Messenger 550 (GAM550) gene, which modulates expression of respective target genes thereof, the function and utility of which target genes is known in the art.

[8033] GAM550 is a novel bioinformatically detected regulatory, non protein coding, micro RNA (miRNA) gene. The method

by which GAM550 was detected is described hereinabove with reference to Figs. 2-8.

[8034] GAM550 gene, herein designated GAM GENE, and GAM550 target gene, herein designated GAM TARGET GENE, are human genes contained in the human genome.

[8035] GAM550 gene, herein designated GAM GENE, encodes a GAM550 precursor RNA, herein designated GAM PRECURSOR RNA. Similar to other miRNA genes, and unlike most ordinary genes, GAM550 precursor RNA, herein designated GAM PRECURSOR RNA, does not encode a protein. A nucleotide sequence identical or highly similar to the nucleotide sequence of GAM550 precursor RNA is designated SEQ ID:8744, and is provided hereinbelow with reference to the sequence listing part.

[8036] GAM550 precursor RNA, herein designated GAM PRECURSOR RNA, folds onto itself, forming GAM550 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, which has a two-dimensional hairpin structure. As is well known in the art, this hairpin structure, is typical of RNA encoded by miRNA genes, and is due to the fact that the nucleotide sequence of the first half of the RNA encoded by a miRNA gene is an accurate or partial inversed-reversed sequence of the nucleotide sequence of the sec-

ond half thereof.

[8037] An enzyme complex designated DICER COMPLEX, dices the GAM550 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, into GAM550 RNA, herein designated GAM RNA, a single stranded ~22 nt long RNA segment. As is known in the art, dicing of a hairpin structured RNA precursor product into a short ~22nt RNA segment is catalyzed by an enzyme complex comprising an enzyme called Dicer together with other necessary proteins. A probable (over 74%) nucleotide sequence of GAM550 RNA is designated SEQ ID:8745, and is provided hereinbelow with reference to the sequence listing part.

[8038] GAM550 target gene, herein designated GAM TARGET GENE, encodes a corresponding messenger RNA, GAM550 target RNA, herein designated GAM TARGET RNA. GAM550 target RNA, herein designated GAM TARGET RNA, comprises three regions, as is typical of mRNA of a protein coding gene: a 5 untranslated region, a protein coding region and a 3 untranslated region, designated 5UTR, PROTEIN CODING and 3UTR respectively.

[8039] GAM550 RNA, herein designated GAM RNA, binds complementarily to one or more target binding sites located in untranslated regions of GAM550 target RNA, herein des-

ignated GAM TARGET RNA. This complementary binding is due to the fact that the nucleotide sequence of GAM550 RNA, herein designated GAM RNA, is an accurate or a partial inversed-reversed sequence of the nucleotide sequence of each of the target binding sites. As an illustration, Fig. 8 shows 3 such target binding sites, designated BINDING SITE I, BINDING SITE II and BINDING SITE III respectively. It is appreciated that the number of target binding sites shown in Fig. 8 is meant as an illustration only, and is not meant to be limiting GAM550 RNA, herein designated GAM RNA, may have a different number of target binding sites in untranslated regions of a GAM550 target RNA, herein designated GAM TARGET RNA. It is further appreciated that while Fig. 8 depicts target binding sites in the 3UTR region, this is meant as an example only these target binding sites may be located in the 3UTR region, the 5UTR region, or in both 3UTR and 5UTR regions.

[8040] The complementary binding of GAM550 RNA, herein designated GAM RNA, to target binding sites on GAM550 target RNA, herein designated GAM TARGET RNA, such as BINDING SITE I, BINDING SITE II and BINDING SITE III, inhibits translation of GAM550 target RNA, herein designated GAM TARGET RNA, into GAM550 target protein,

herein designated GAM TARGET PROTEIN. GAM target protein is therefore outlined by a broken line.

[8041] It is appreciated that GAM550 target gene, herein designated GAM TARGET GENE, in fact represents a plurality of GAM550 target genes. The mRNA of each one of this plurality of GAM550 target genes comprises one or more target binding sites, each having a nucleotide sequence which is at least partly complementary to GAM550 RNA, herein designated GAM RNA, and which when bound by GAM550 RNA, herein designated GAM RNA, causes inhibition of translation of respective one or more GAM550 target proteins.

[8042] It is further appreciated by one skilled in the art that the mode of translational inhibition illustrated by Fig. 8 with specific reference to translational inhibition exerted by GAM550 gene, herein designated GAM GENE, on one or more GAM550 target gene, herein designated GAM TARGET GENE, is in fact common to other known miRNA genes. As mentioned hereinabove with reference to the background section, although a specific complementary binding site has been demonstrated only for some of the known miRNA genes (primarily Lin-4 and Let-7), all other recently discovered miRNA genes are also believed by

those skilled in the art to modulate expression of other genes by complementary binding, although specific complementary binding sites of these other miRNA genes have not yet been found (Ruvkun G., Perspective: Glimpses of a tiny RNA world, Science 294,779 (2001)).

[8043] It is yet further appreciated that specific functions, and accordingly utilities, of GAM550 correlate with, and may be deduced from, the identity of the target genes which GAM550 binds and inhibits, and the function of these target genes, as elaborated hereinbelow.

[8044] Nucleotide sequences of the GAM550 precursor RNA, herein designated GAM PRECURSOR RNA, and of the diced GAM550 RNA, herein designated GAM RNA, and a schematic representation of the secondary folding of GAM550 folded precursor RNA, herein designated GAM FOLDED PRECURSOR RNA, of GAM550 are further described hereinbelow with reference to Table Table1.

[8045] Nucleotide sequences of target binding sites, such as BINDING SITE-I, BINDING SITE-II and BINDING SITE-III of Fig. 8, found on, and schematic representation of the complementarity of each of these target binding sites to GAM550 RNA, herein designated GAM RNA, are described hereinbelow with reference to Table Table2.

[8046]

[8047] Reference is now made to Fig. 11, which is a simplified diagram describing each of a plurality of novel bioinformatically detected regulatory genes, referred to here as Genomic Record(GR) genes, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8048] GR GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR GENE was detected is described hereinabove with reference to Figs. 6-15.

[8049] GR GENE encodes GR PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8050] GR PRECURSOR RNA folds spatially, forming GR FOLDED PRECURSOR RNA. It is appreciated that GR FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the sec-

ond half thereof, as is well known in the art.

[8051] GR FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into a plurality of separate GAM precursor RNAs, schematically represented by GAM1 PRECURSOR, GAM2 PRECURSOR, GAM3 PRECURSOR, GAM4 PRECURSOR, GAM5 PRECURSOR, GAM6 PRECURSOR, GAM7 PRECURSOR and GAM8 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8052] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, schematically represented as GAM1 RNA, GAM2 RNA, GAM3 RNA, GAM4 RNA, GAM5 RNA, GAM6 RNA, GAM7 RNA and GAM8 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8053] GAM1 RNA binds complimentarily to a target binding site located in an untranslated region of GAM1 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM1 TARGET RNA into GAM1 TARGET PROTEIN, both of Fig. 10.

[8054] GAM2 RNA binds complimentarily to a target binding site

located in an untranslated region of GAM2 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM2 TARGET RNA into GAM2 TARGET PROTEIN, both of Fig. 10.

[8055] GAM3 RNA binds complimentarily to a target binding site located in an untranslated region of GAM3 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM3 TARGET RNA into GAM3 TARGET PROTEIN, both of Fig. 10.

[8056] GAM4 RNA binds complimentarily to a target binding site located in an untranslated region of GAM4 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM4 TARGET RNA into GAM4 TARGET PROTEIN, both of Fig. 10.

[8057] GAM5 RNA binds complimentarily to a target binding site located in an untranslated region of GAM5 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM5 TARGET RNA into GAM5 TARGET PROTEIN, both of Fig. 10.

[8058] GAM6 RNA binds complimentarily to a target binding site located in an untranslated region of GAM6 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM6 TARGET RNA into GAM6 TARGET PROTEIN, both of Fig. 10.

[8059] GAM7 RNA binds complimentarily to a target binding site located in an untranslated region of GAM7 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM7 TARGET RNA into GAM7 TARGET PROTEIN, both of Fig. 10.

[8060] GAM8 RNA binds complimentarily to a target binding site located in an untranslated region of GAM8 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 10, thereby inhibiting translation of GAM8 TARGET RNA into GAM8 TARGET PROTEIN, both of Fig. 10.

[8061] It is appreciated that specific functions, and accordingly utilities, of GR GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR GENE, schematically represented by GAM1 TARGET PRO-

TEIN through GAM8 TARGET PROTEIN.

[8062] Reference is now made to Fig. 551, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 551(GR551) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8063] GR551 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR551 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8064] GR551 GENE encodes GR551 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8065] GR551 PRECURSOR RNA folds spatially, forming GR551 FOLDED PRECURSOR RNA . It is appreciated that GR551 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR551 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-re-

versed sequence of the second half thereof, as is well known in the art.

[8066] GR551 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8067] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8068] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8069] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8070] It is appreciated that specific functions, and accordingly utilities, of GR551 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR551 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8071] Reference is now made to Fig. 552, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 552(GR552) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8072] GR552 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR552 GENE was detected is described hereinabove with

reference to Figs. 6-15.

[8073] GR552 GENE encodes GR552 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8074] GR552 PRECURSOR RNA folds spatially, forming GR552 FOLDED PRECURSOR RNA . It is appreciated that GR552 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR552 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8075] GR552 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM103 PRECURSOR and GAM312 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8076] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM103 RNA and GAM312 RNA respectively, each of which GAM RNAs

corresponding to GAM RNA of Fig. 8.

[8077] GAM103 RNA binds complimentarily to a target binding site located in an untranslated region of GAM103 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 103A, thereby inhibiting translation of GAM103 TARGET RNA into GAM103 TARGET PROTEIN, both of Fig. 103A.

[8078] GAM312 RNA binds complimentarily to a target binding site located in an untranslated region of GAM312 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 312A, thereby inhibiting translation of GAM312 TARGET RNA into GAM312 TARGET PROTEIN, both of Fig. 312A.

[8079] It is appreciated that specific functions, and accordingly utilities, of GR552 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR552 GENE: GAM103 TARGET PROTEIN and GAM312 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 103D and 312D

[8080] Reference is now made to Fig. 553, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 553(GR553) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8081] GR553 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR553 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8082] GR553 GENE encodes GR553 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8083] GR553 PRECURSOR RNA folds spatially, forming GR553 FOLDED PRECURSOR RNA . It is appreciated that GR553 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR553 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well

known in the art.

[8084] GR553 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM269 PRECURSOR and GAM372 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8085] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM269 RNA and GAM372 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8086] GAM269 RNA binds complimentarily to a target binding site located in an untranslated region of GAM269 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 269A, thereby inhibiting translation of GAM269 TARGET RNA into GAM269 TARGET PROTEIN, both of Fig. 269A.

[8087] GAM372 RNA binds complimentarily to a target binding site located in an untranslated region of GAM372 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 372A, thereby inhibiting translation of GAM372 TARGET RNA into GAM372 TARGET PROTEIN, both of Fig. 372A.

[8088] It is appreciated that specific functions, and accordingly utilities, of GR553 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR553 GENE: GAM269 TARGET PROTEIN and GAM372 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 269D and 372D

[8089] Reference is now made to Fig. 554, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 554(GR554) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8090] GR554 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR554 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8091] GR554 GENE encodes GR554 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8092] GR554 PRECURSOR RNA folds spatially, forming GR554 FOLDED PRECURSOR RNA . It is appreciated that GR554 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR554 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8093] GR554 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM150 PRECURSOR and GAM542 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8094] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM150 RNA and GAM542 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8095] GAM150 RNA binds complimentarily to a target binding site located in an untranslated region of GAM150 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 150A, thereby inhibiting translation of GAM150 TARGET RNA into GAM150 TARGET PROTEIN, both of Fig. 150A.

[8096] GAM542 RNA binds complimentarily to a target binding site located in an untranslated region of GAM542 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 542A, thereby inhibiting translation of GAM542 TARGET RNA into GAM542 TARGET PROTEIN, both of Fig. 542A.

[8097] It is appreciated that specific functions, and accordingly utilities, of GR554 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR554 GENE: GAM150 TARGET PROTEIN and GAM542 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 150D and 542D

[8098] Reference is now made to Fig. 555, which is a simplified

diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 555(GR555) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8099] GR555 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR555 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8100] GR555 GENE encodes GR555 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8101] GR555 PRECURSOR RNA folds spatially, forming GR555 FOLDED PRECURSOR RNA . It is appreciated that GR555 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR555 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8102] GR555 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM293 PRECURSOR and GAM368 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8103] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM293 RNA and GAM368 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8104] GAM293 RNA binds complimentarily to a target binding site located in an untranslated region of GAM293 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 293A, thereby inhibiting translation of GAM293 TARGET RNA into GAM293 TARGET PROTEIN, both of Fig. 293A.

[8105] GAM368 RNA binds complimentarily to a target binding site located in an untranslated region of GAM368 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 368A, thereby inhibiting transla-

tion of GAM368 TARGET RNA into GAM368 TARGET PROTEIN, both of Fig. 368A.

[8106] It is appreciated that specific functions, and accordingly utilities, of GR555 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR555 GENE: GAM293 TARGET PROTEIN and GAM368 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 293D and 368D

[8107] Reference is now made to Fig. 556, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 556(GR556) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8108] GR556 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR556 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8109] GR556 GENE encodes GR556 PRECURSOR RNA, an RNA

molecule, typically several hundred nucleotides long.

[8110] GR556 PRECURSOR RNA folds spatially, forming GR556 FOLDED PRECURSOR RNA . It is appreciated that GR556 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR556 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8111] GR556 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM515 PRECURSOR and GAM516 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8112] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM515 RNA and GAM516 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8113] GAM515 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM515 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 515A, thereby inhibiting translation of GAM515 TARGET RNA into GAM515 TARGET PROTEIN, both of Fig. 515A.

[8114] GAM516 RNA binds complimentarily to a target binding site located in an untranslated region of GAM516 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 516A, thereby inhibiting translation of GAM516 TARGET RNA into GAM516 TARGET PROTEIN, both of Fig. 516A.

[8115] It is appreciated that specific functions, and accordingly utilities, of GR556 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR556 GENE: GAM515 TARGET PROTEIN and GAM516 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 515D and 516D

[8116] Reference is now made to Fig. 557, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 557(GR557) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8117] GR557 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR557 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8118] GR557 GENE encodes GR557 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8119] GR557 PRECURSOR RNA folds spatially, forming GR557 FOLDED PRECURSOR RNA . It is appreciated that GR557 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR557 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8120] GR557 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM85 PRECURSOR and GAM121 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8121] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM85 RNA and GAM121 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8122] GAM85 RNA binds complimentarily to a target binding site located in an untranslated region of GAM85 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 85A, thereby inhibiting translation of GAM85 TARGET RNA into GAM85 TARGET PROTEIN, both of Fig. 85A.

[8123] GAM121 RNA binds complimentarily to a target binding site located in an untranslated region of GAM121 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 121A, thereby inhibiting translation of GAM121 TARGET RNA into GAM121 TARGET PRO-

TEIN, both of Fig. 121A.

[8124] It is appreciated that specific functions, and accordingly utilities, of GR557 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR557 GENE: GAM85 TARGET PROTEIN and GAM121 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 85D and 121D

[8125] Reference is now made to Fig. 558, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 558(GR558) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8126] GR558 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR558 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8127] GR558 GENE encodes GR558 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8128] GR558 PRECURSOR RNA folds spatially, forming GR558 FOLDED PRECURSOR RNA . It is appreciated that GR558 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR558 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8129] GR558 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM266 PRECURSOR, GAM357 PRECURSOR and GAM504 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8130] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM266 RNA, GAM357 RNA and GAM504 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8131] GAM266 RNA binds complimentarily to a target binding site located in an untranslated region of GAM266 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 266A, thereby inhibiting translation of GAM266 TARGET RNA into GAM266 TARGET PROTEIN, both of Fig. 266A.

[8132] GAM357 RNA binds complimentarily to a target binding site located in an untranslated region of GAM357 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 357A, thereby inhibiting translation of GAM357 TARGET RNA into GAM357 TARGET PROTEIN, both of Fig. 357A.

[8133] GAM504 RNA binds complimentarily to a target binding site located in an untranslated region of GAM504 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 504A, thereby inhibiting translation of GAM504 TARGET RNA into GAM504 TARGET PROTEIN, both of Fig. 504A.

[8134] It is appreciated that specific functions, and accordingly utilities, of GR558 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR558 GENE: GAM266 TARGET PROTEIN, GAM357 TARGET PROTEIN and GAM504 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 266D, 357D and 504D

[8135] Reference is now made to Fig. 559, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 559(GR559) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8136] GR559 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR559 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8137] GR559 GENE encodes GR559 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8138] GR559 PRECURSOR RNA folds spatially, forming GR559 FOLDED PRECURSOR RNA . It is appreciated that GR559 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR559 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8139] GR559 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM41 PRECURSOR, GAM45 PRECURSOR and GAM179 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8140] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM41 RNA, GAM45 RNA and GAM179 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8141] GAM41 RNA binds complimentarily to a target binding site located in an untranslated region of GAM41 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 41A, thereby inhibiting translation of GAM41 TARGET RNA into GAM41 TARGET PROTEIN, both of Fig. 41A.

[8142] GAM45 RNA binds complimentarily to a target binding site located in an untranslated region of GAM45 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 45A, thereby inhibiting translation of GAM45 TARGET RNA into GAM45 TARGET PROTEIN, both of Fig. 45A.

[8143] GAM179 RNA binds complimentarily to a target binding site located in an untranslated region of GAM179 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 179A, thereby inhibiting translation of GAM179 TARGET RNA into GAM179 TARGET PROTEIN, both of Fig. 179A.

[8144] It is appreciated that specific functions, and accordingly utilities, of GR559 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR559 GENE: GAM41 TARGET PROTEIN, GAM45 TARGET PROTEIN and GAM179 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 41D, 45D and 179D

[8145] Reference is now made to Fig. 560, which is a simplified

diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 560(GR560) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8146] GR560 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR560 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8147] GR560 GENE encodes GR560 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8148] GR560 PRECURSOR RNA folds spatially, forming GR560 FOLDED PRECURSOR RNA . It is appreciated that GR560 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR560 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8149] GR560 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8150] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8151] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8152] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting transla-

tion of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8153] It is appreciated that specific functions, and accordingly utilities, of GR560 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR560 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8154] Reference is now made to Fig. 561, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 561(GR561) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8155] GR561 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR561 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8156] GR561 GENE encodes GR561 PRECURSOR RNA, an RNA

molecule, typically several hundred nucleotides long.

[8157] GR561 PRECURSOR RNA folds spatially, forming GR561 FOLDED PRECURSOR RNA . It is appreciated that GR561 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR561 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8158] GR561 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM212 PRECURSOR and GAM493 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8159] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM212 RNA and GAM493 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8160] GAM212 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM212 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 212A, thereby inhibiting translation of GAM212 TARGET RNA into GAM212 TARGET PROTEIN, both of Fig. 212A.

[8161] GAM493 RNA binds complimentarily to a target binding site located in an untranslated region of GAM493 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 493A, thereby inhibiting translation of GAM493 TARGET RNA into GAM493 TARGET PROTEIN, both of Fig. 493A.

[8162] It is appreciated that specific functions, and accordingly utilities, of GR561 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR561 GENE: GAM212 TARGET PROTEIN and GAM493 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 212D and 493D

[8163] Reference is now made to Fig. 562, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 562(GR562) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8164] GR562 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR562 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8165] GR562 GENE encodes GR562 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8166] GR562 PRECURSOR RNA folds spatially, forming GR562 FOLDED PRECURSOR RNA . It is appreciated that GR562 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR562 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8167] GR562 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM35 PRECURSOR and GAM513 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8168] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM35 RNA and GAM513 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8169] GAM35 RNA binds complimentarily to a target binding site located in an untranslated region of GAM35 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 35A, thereby inhibiting translation of GAM35 TARGET RNA into GAM35 TARGET PROTEIN, both of Fig. 35A.

[8170] GAM513 RNA binds complimentarily to a target binding site located in an untranslated region of GAM513 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 513A, thereby inhibiting translation of GAM513 TARGET RNA into GAM513 TARGET PROTEIN, both of Fig. 513A.

[8171] It is appreciated that specific functions, and accordingly utilities, of GR562 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR562 GENE: GAM35 TARGET PROTEIN and GAM513 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 35D and 513D

[8172] Reference is now made to Fig. 563, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 563(GR563) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8173] GR563 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR563 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8174] GR563 GENE encodes GR563 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8175] GR563 PRECURSOR RNA folds spatially, forming GR563 FOLDED PRECURSOR RNA . It is appreciated that GR563 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR563 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8176] GR563 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM224 PRECURSOR and GAM262 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8177] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM224 RNA and GAM262 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8178] GAM224 RNA binds complimentarily to a target binding site located in an untranslated region of GAM224 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 224A, thereby inhibiting translation of GAM224 TARGET RNA into GAM224 TARGET PROTEIN, both of Fig. 224A.

[8179] GAM262 RNA binds complimentarily to a target binding site located in an untranslated region of GAM262 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 262A, thereby inhibiting translation of GAM262 TARGET RNA into GAM262 TARGET PROTEIN, both of Fig. 262A.

[8180] It is appreciated that specific functions, and accordingly utilities, of GR563 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR563 GENE: GAM224 TARGET PROTEIN and GAM262 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 224D and 262D

[8181] Reference is now made to Fig. 564, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 564(GR564) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8182] GR564 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR564 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8183] GR564 GENE encodes GR564 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8184] GR564 PRECURSOR RNA folds spatially, forming GR564 FOLDED PRECURSOR RNA . It is appreciated that GR564 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR564 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8185] GR564 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM263 PRECURSOR and GAM385 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8186] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM263 RNA and GAM385 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8187] GAM263 RNA binds complimentarily to a target binding site located in an untranslated region of GAM263 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 263A, thereby inhibiting translation of GAM263 TARGET RNA into GAM263 TARGET PROTEIN, both of Fig. 263A.

[8188] GAM385 RNA binds complimentarily to a target binding site located in an untranslated region of GAM385 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 385A, thereby inhibiting translation of GAM385 TARGET RNA into GAM385 TARGET PROTEIN, both of Fig. 385A.

[8189] It is appreciated that specific functions, and accordingly utilities, of GR564 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR564 GENE: GAM263 TARGET PROTEIN and GAM385

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 263D and 385D

[8190] Reference is now made to Fig. 565, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 565(GR565) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8191] GR565 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR565 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8192] GR565 GENE encodes GR565 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8193] GR565 PRECURSOR RNA folds spatially, forming GR565 FOLDED PRECURSOR RNA . It is appreciated that GR565 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR565 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8194] GR565 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM431 PRECURSOR and GAM531 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8195] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM431 RNA and GAM531 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8196] GAM431 RNA binds complimentarily to a target binding site located in an untranslated region of GAM431 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 431A, thereby inhibiting translation of GAM431 TARGET RNA into GAM431 TARGET PROTEIN, both of Fig. 431A.

[8197] GAM531 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM531 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 531A, thereby inhibiting translation of GAM531 TARGET RNA into GAM531 TARGET PROTEIN, both of Fig. 531A.

[8198] It is appreciated that specific functions, and accordingly utilities, of GR565 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR565 GENE: GAM431 TARGET PROTEIN and GAM531 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 431D and 531D

[8199] Reference is now made to Fig. 566, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 566(GR566) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8200] GR566 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR566 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8201] GR566 GENE encodes GR566 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8202] GR566 PRECURSOR RNA folds spatially, forming GR566 FOLDED PRECURSOR RNA . It is appreciated that GR566 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR566 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8203] GR566 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM473 PRECURSOR and GAM477 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8204] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM473 RNA and GAM477 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8205] GAM473 RNA binds complimentarily to a target binding site located in an untranslated region of GAM473 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 473A, thereby inhibiting translation of GAM473 TARGET RNA into GAM473 TARGET PROTEIN, both of Fig. 473A.

[8206] GAM477 RNA binds complimentarily to a target binding site located in an untranslated region of GAM477 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 477A, thereby inhibiting translation of GAM477 TARGET RNA into GAM477 TARGET PROTEIN, both of Fig. 477A.

[8207] It is appreciated that specific functions, and accordingly utilities, of GR566 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR566 GENE: GAM473 TARGET PROTEIN and GAM477 TARGET PROTEIN. The function of these target genes is

elaborated hereinabove with reference to Figs. 473D and 477D

[8208] Reference is now made to Fig. 567, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 567(GR567) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8209] GR567 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR567 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8210] GR567 GENE encodes GR567 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8211] GR567 PRECURSOR RNA folds spatially, forming GR567 FOLDED PRECURSOR RNA . It is appreciated that GR567 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR567 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nu-

cleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8212] GR567 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM480 PRECURSOR and GAM508 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8213] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM480 RNA and GAM508 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8214] GAM480 RNA binds complimentarily to a target binding site located in an untranslated region of GAM480 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 480A, thereby inhibiting translation of GAM480 TARGET RNA into GAM480 TARGET PROTEIN, both of Fig. 480A.

[8215] GAM508 RNA binds complimentarily to a target binding site located in an untranslated region of GAM508 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 508A, thereby inhibiting translation of GAM508 TARGET RNA into GAM508 TARGET PROTEIN, both of Fig. 508A.

[8216] It is appreciated that specific functions, and accordingly utilities, of GR567 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR567 GENE: GAM480 TARGET PROTEIN and GAM508 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 480D and 508D

[8217] Reference is now made to Fig. 568, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 568(GR568) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8218] GR568 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which

GR568 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8219] GR568 GENE encodes GR568 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8220] GR568 PRECURSOR RNA folds spatially, forming GR568 FOLDED PRECURSOR RNA . It is appreciated that GR568 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR568 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8221] GR568 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM163 PRECURSOR and GAM369 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8222] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM163 RNA

and GAM369 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8223] GAM163 RNA binds complimentarily to a target binding site located in an untranslated region of GAM163 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 163A, thereby inhibiting translation of GAM163 TARGET RNA into GAM163 TARGET PROTEIN, both of Fig. 163A.

[8224] GAM369 RNA binds complimentarily to a target binding site located in an untranslated region of GAM369 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 369A, thereby inhibiting translation of GAM369 TARGET RNA into GAM369 TARGET PROTEIN, both of Fig. 369A.

[8225] It is appreciated that specific functions, and accordingly utilities, of GR568 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR568 GENE: GAM163 TARGET PROTEIN and GAM369 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 163D and

[8226] Reference is now made to Fig. 569, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 569(GR569) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8227] GR569 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR569 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8228] GR569 GENE encodes GR569 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8229] GR569 PRECURSOR RNA folds spatially, forming GR569 FOLDED PRECURSOR RNA . It is appreciated that GR569 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR569 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-re-

versed sequence of the second half thereof, as is well known in the art.

[8230] GR569 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM167 PRECURSOR and GAM499 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8231] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM167 RNA and GAM499 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8232] GAM167 RNA binds complimentarily to a target binding site located in an untranslated region of GAM167 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 167A, thereby inhibiting translation of GAM167 TARGET RNA into GAM167 TARGET PROTEIN, both of Fig. 167A.

[8233] GAM499 RNA binds complimentarily to a target binding site located in an untranslated region of GAM499 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 499A, thereby inhibiting translation of GAM499 TARGET RNA into GAM499 TARGET PROTEIN, both of Fig. 499A.

[8234] It is appreciated that specific functions, and accordingly utilities, of GR569 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR569 GENE: GAM167 TARGET PROTEIN and GAM499 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 167D and 499D

[8235] Reference is now made to Fig. 570, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 570(GR570) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8236] GR570 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR570 GENE was detected is described hereinabove with

reference to Figs. 6-15.

[8237] GR570 GENE encodes GR570 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8238] GR570 PRECURSOR RNA folds spatially, forming GR570 FOLDED PRECURSOR RNA . It is appreciated that GR570 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR570 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8239] GR570 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8240] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs

corresponding to GAM RNA of Fig. 8.

[8241] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8242] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8243] It is appreciated that specific functions, and accordingly utilities, of GR570 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR570 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8244] Reference is now made to Fig. 571, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 571(GR571) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8245] GR571 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR571 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8246] GR571 GENE encodes GR571 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8247] GR571 PRECURSOR RNA folds spatially, forming GR571 FOLDED PRECURSOR RNA . It is appreciated that GR571 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR571 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well

known in the art.

[8248] GR571 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM318 PRECURSOR and GAM320 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8249] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM318 RNA and GAM320 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8250] GAM318 RNA binds complimentarily to a target binding site located in an untranslated region of GAM318 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 318A, thereby inhibiting translation of GAM318 TARGET RNA into GAM318 TARGET PROTEIN, both of Fig. 318A.

[8251] GAM320 RNA binds complimentarily to a target binding site located in an untranslated region of GAM320 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 320A, thereby inhibiting translation of GAM320 TARGET RNA into GAM320 TARGET PROTEIN, both of Fig. 320A.

[8252] It is appreciated that specific functions, and accordingly utilities, of GR571 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR571 GENE: GAM318 TARGET PROTEIN and GAM320 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 318D and 320D

[8253] Reference is now made to Fig. 572, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 572(GR572) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8254] GR572 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR572 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8255] GR572 GENE encodes GR572 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8256] GR572 PRECURSOR RNA folds spatially, forming GR572 FOLDED PRECURSOR RNA . It is appreciated that GR572 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR572 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8257] GR572 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM166 PRECURSOR, GAM255 PRECURSOR and GAM438 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8258] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM166 RNA, GAM255 RNA and GAM438 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8259] GAM166 RNA binds complimentarily to a target binding site located in an untranslated region of GAM166 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 166A, thereby inhibiting translation of GAM166 TARGET RNA into GAM166 TARGET PROTEIN, both of Fig. 166A.

[8260] GAM255 RNA binds complimentarily to a target binding site located in an untranslated region of GAM255 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 255A, thereby inhibiting translation of GAM255 TARGET RNA into GAM255 TARGET PROTEIN, both of Fig. 255A.

[8261] GAM438 RNA binds complimentarily to a target binding site located in an untranslated region of GAM438 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 438A, thereby inhibiting translation of GAM438 TARGET RNA into GAM438 TARGET PROTEIN, both of Fig. 438A.

[8262] It is appreciated that specific functions, and accordingly utilities, of GR572 GENE correlate with, and may be de-

duced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR572 GENE: GAM166 TARGET PROTEIN, GAM255 TARGET PROTEIN and GAM438 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 166D, 255D and 438D

[8263] Reference is now made to Fig. 573, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 573(GR573) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8264] GR573 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR573 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8265] GR573 GENE encodes GR573 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8266] GR573 PRECURSOR RNA folds spatially, forming GR573 FOLDED PRECURSOR RNA . It is appreciated that GR573 FOLDED PRECURSOR RNA comprises a plurality of what is

known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR573 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8267] GR573 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM182 PRECURSOR and GAM287 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8268] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM182 RNA and GAM287 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8269] GAM182 RNA binds complimentarily to a target binding site located in an untranslated region of GAM182 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 182A, thereby inhibiting transla-

tion of GAM182 TARGET RNA into GAM182 TARGET PROTEIN, both of Fig. 182A.

[8270] GAM287 RNA binds complimentarily to a target binding site located in an untranslated region of GAM287 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 287A, thereby inhibiting translation of GAM287 TARGET RNA into GAM287 TARGET PROTEIN, both of Fig. 287A.

[8271] It is appreciated that specific functions, and accordingly utilities, of GR573 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR573 GENE: GAM182 TARGET PROTEIN and GAM287 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 182D and 287D

[8272] Reference is now made to Fig. 574, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 574(GR574) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the

function and utility of which at least one target gene is known in the art.

[8273] GR574 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR574 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8274] GR574 GENE encodes GR574 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8275] GR574 PRECURSOR RNA folds spatially, forming GR574 FOLDED PRECURSOR RNA . It is appreciated that GR574 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR574 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8276] GR574 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM305 PRECURSOR and GAM329 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECUR-

SOR RNA of Fig. 8.

[8277] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM305 RNA and GAM329 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8278] GAM305 RNA binds complimentarily to a target binding site located in an untranslated region of GAM305 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 305A, thereby inhibiting translation of GAM305 TARGET RNA into GAM305 TARGET PROTEIN, both of Fig. 305A.

[8279] GAM329 RNA binds complimentarily to a target binding site located in an untranslated region of GAM329 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 329A, thereby inhibiting translation of GAM329 TARGET RNA into GAM329 TARGET PROTEIN, both of Fig. 329A.

[8280] It is appreciated that specific functions, and accordingly utilities, of GR574 GENE correlate with, and may be deduced from, the identity of the target genes, which are in-

hibited by GAM RNAs comprised in the operon-like cluster of GR574 GENE: GAM305 TARGET PROTEIN and GAM329 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 305D and 329D

[8281] Reference is now made to Fig. 575, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 575(GR575) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8282] GR575 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR575 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8283] GR575 GENE encodes GR575 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8284] GR575 PRECURSOR RNA folds spatially, forming GR575 FOLDED PRECURSOR RNA . It is appreciated that GR575 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin

structures are due to the fact that the nucleotide sequence of GR575 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8285] GR575 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM165 PRECURSOR and GAM506 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8286] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM165 RNA and GAM506 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8287] GAM165 RNA binds complimentarily to a target binding site located in an untranslated region of GAM165 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 165A, thereby inhibiting translation of GAM165 TARGET RNA into GAM165 TARGET PRO-

TEIN, both of Fig. 165A.

[8288] GAM506 RNA binds complimentarily to a target binding site located in an untranslated region of GAM506 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 506A, thereby inhibiting translation of GAM506 TARGET RNA into GAM506 TARGET PROTEIN, both of Fig. 506A.

[8289] It is appreciated that specific functions, and accordingly utilities, of GR575 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR575 GENE: GAM165 TARGET PROTEIN and GAM506 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 165D and 506D

[8290] Reference is now made to Fig. 576, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 576(GR576) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is

known in the art.

[8291] GR576 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR576 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8292] GR576 GENE encodes GR576 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8293] GR576 PRECURSOR RNA folds spatially, forming GR576 FOLDED PRECURSOR RNA . It is appreciated that GR576 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR576 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8294] GR576 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM181 PRECURSOR and GAM392 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8295] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM181 RNA and GAM392 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8296] GAM181 RNA binds complimentarily to a target binding site located in an untranslated region of GAM181 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 181A, thereby inhibiting translation of GAM181 TARGET RNA into GAM181 TARGET PROTEIN, both of Fig. 181A.

[8297] GAM392 RNA binds complimentarily to a target binding site located in an untranslated region of GAM392 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 392A, thereby inhibiting translation of GAM392 TARGET RNA into GAM392 TARGET PROTEIN, both of Fig. 392A.

[8298] It is appreciated that specific functions, and accordingly utilities, of GR576 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR576 GENE: GAM181 TARGET PROTEIN and GAM392 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 181D and 392D

[8299] Reference is now made to Fig. 577, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 577(GR577) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8300] GR577 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR577 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8301] GR577 GENE encodes GR577 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8302] GR577 PRECURSOR RNA folds spatially, forming GR577 FOLDED PRECURSOR RNA . It is appreciated that GR577 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR577 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8303] GR577 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM249 PRECURSOR and GAM384 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8304] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM249 RNA and GAM384 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8305] GAM249 RNA binds complimentarily to a target binding site located in an untranslated region of GAM249 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 249A, thereby inhibiting translation of GAM249 TARGET RNA into GAM249 TARGET PROTEIN, both of Fig. 249A.

[8306] GAM384 RNA binds complimentarily to a target binding site located in an untranslated region of GAM384 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 384A, thereby inhibiting translation of GAM384 TARGET RNA into GAM384 TARGET PROTEIN, both of Fig. 384A.

[8307] It is appreciated that specific functions, and accordingly utilities, of GR577 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR577 GENE: GAM249 TARGET PROTEIN and GAM384 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 249D and 384D

[8308] Reference is now made to Fig. 578, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 578(GR578) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8309] GR578 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR578 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8310] GR578 GENE encodes GR578 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8311] GR578 PRECURSOR RNA folds spatially, forming GR578 FOLDED PRECURSOR RNA . It is appreciated that GR578 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR578 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8312] GR578 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM526 PRECURSOR and GAM541 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8313] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM526 RNA and GAM541 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8314] GAM526 RNA binds complimentarily to a target binding site located in an untranslated region of GAM526 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 526A, thereby inhibiting translation of GAM526 TARGET RNA into GAM526 TARGET PROTEIN, both of Fig. 526A.

[8315] GAM541 RNA binds complimentarily to a target binding site located in an untranslated region of GAM541 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 541A, thereby inhibiting translation of GAM541 TARGET RNA into GAM541 TARGET PROTEIN, both of Fig. 541A.

[8316] It is appreciated that specific functions, and accordingly utilities, of GR578 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR578 GENE: GAM526 TARGET PROTEIN and GAM541

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 526D and 541D

[8317] Reference is now made to Fig. 579, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 579(GR579) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8318] GR579 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR579 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8319] GR579 GENE encodes GR579 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8320] GR579 PRECURSOR RNA folds spatially, forming GR579 FOLDED PRECURSOR RNA . It is appreciated that GR579 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR579 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8321] GR579 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM323 PRECURSOR and GAM529 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8322] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM323 RNA and GAM529 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8323] GAM323 RNA binds complimentarily to a target binding site located in an untranslated region of GAM323 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 323A, thereby inhibiting translation of GAM323 TARGET RNA into GAM323 TARGET PROTEIN, both of Fig. 323A.

[8324] GAM529 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM529 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 529A, thereby inhibiting translation of GAM529 TARGET RNA into GAM529 TARGET PROTEIN, both of Fig. 529A.

[8325] It is appreciated that specific functions, and accordingly utilities, of GR579 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR579 GENE: GAM323 TARGET PROTEIN and GAM529 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 323D and 529D

[8326] Reference is now made to Fig. 580, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 580(GR580) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8327] GR580 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR580 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8328] GR580 GENE encodes GR580 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8329] GR580 PRECURSOR RNA folds spatially, forming GR580 FOLDED PRECURSOR RNA . It is appreciated that GR580 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR580 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8330] GR580 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM91 PRECURSOR and GAM465 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8331] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM91 RNA and GAM465 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8332] GAM91 RNA binds complimentarily to a target binding site located in an untranslated region of GAM91 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 91A, thereby inhibiting translation of GAM91 TARGET RNA into GAM91 TARGET PROTEIN, both of Fig. 91A.

[8333] GAM465 RNA binds complimentarily to a target binding site located in an untranslated region of GAM465 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 465A, thereby inhibiting translation of GAM465 TARGET RNA into GAM465 TARGET PROTEIN, both of Fig. 465A.

[8334] It is appreciated that specific functions, and accordingly utilities, of GR580 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR580 GENE: GAM91 TARGET PROTEIN and GAM465 TARGET PROTEIN. The function of these target genes is

elaborated hereinabove with reference to Figs. 91D and 465D

[8335] Reference is now made to Fig. 581, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 581(GR581) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8336] GR581 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR581 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8337] GR581 GENE encodes GR581 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8338] GR581 PRECURSOR RNA folds spatially, forming GR581 FOLDED PRECURSOR RNA . It is appreciated that GR581 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR581 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nu-

cleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8339] GR581 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM44 PRECURSOR and GAM403 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8340] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM44 RNA and GAM403 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8341] GAM44 RNA binds complimentarily to a target binding site located in an untranslated region of GAM44 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 44A, thereby inhibiting translation of GAM44 TARGET RNA into GAM44 TARGET PROTEIN, both of Fig. 44A.

[8342] GAM403 RNA binds complimentarily to a target binding site located in an untranslated region of GAM403 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 403A, thereby inhibiting translation of GAM403 TARGET RNA into GAM403 TARGET PROTEIN, both of Fig. 403A.

[8343] It is appreciated that specific functions, and accordingly utilities, of GR581 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR581 GENE: GAM44 TARGET PROTEIN and GAM403 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 44D and 403D

[8344] Reference is now made to Fig. 582, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 582(GR582) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8345] GR582 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which

GR582 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8346] GR582 GENE encodes GR582 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8347] GR582 PRECURSOR RNA folds spatially, forming GR582 FOLDED PRECURSOR RNA . It is appreciated that GR582 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR582 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8348] GR582 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM67 PRECURSOR, GAM295 PRECURSOR and GAM331 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8349] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM67 RNA,

GAM295 RNA and GAM331 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8350] GAM67 RNA binds complimentarily to a target binding site located in an untranslated region of GAM67 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 67A, thereby inhibiting translation of GAM67 TARGET RNA into GAM67 TARGET PROTEIN, both of Fig. 67A.

[8351] GAM295 RNA binds complimentarily to a target binding site located in an untranslated region of GAM295 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 295A, thereby inhibiting translation of GAM295 TARGET RNA into GAM295 TARGET PROTEIN, both of Fig. 295A.

[8352] GAM331 RNA binds complimentarily to a target binding site located in an untranslated region of GAM331 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 331A, thereby inhibiting translation of GAM331 TARGET RNA into GAM331 TARGET PROTEIN, both of Fig. 331A.

[8353] It is appreciated that specific functions, and accordingly utilities, of GR582 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR582 GENE: GAM67 TARGET PROTEIN, GAM295 TARGET PROTEIN and GAM331 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 67D, 295D and 331D

[8354] Reference is now made to Fig. 583, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 583(GR583) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8355] GR583 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR583 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8356] GR583 GENE encodes GR583 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8357] GR583 PRECURSOR RNA folds spatially, forming GR583

FOLDED PRECURSOR RNA . It is appreciated that GR583 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR583 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8358] GR583 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM189 PRECURSOR and GAM251 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8359] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM189 RNA and GAM251 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8360] GAM189 RNA binds complimentarily to a target binding site located in an untranslated region of GAM189 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 189A, thereby inhibiting translation of GAM189 TARGET RNA into GAM189 TARGET PROTEIN, both of Fig. 189A.

[8361] GAM251 RNA binds complimentarily to a target binding site located in an untranslated region of GAM251 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 251A, thereby inhibiting translation of GAM251 TARGET RNA into GAM251 TARGET PROTEIN, both of Fig. 251A.

[8362] It is appreciated that specific functions, and accordingly utilities, of GR583 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR583 GENE: GAM189 TARGET PROTEIN and GAM251 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 189D and 251D

[8363] Reference is now made to Fig. 584, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 584(GR584) gene, which encodes an operon-like cluster

of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8364] GR584 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR584 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8365] GR584 GENE encodes GR584 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8366] GR584 PRECURSOR RNA folds spatially, forming GR584 FOLDED PRECURSOR RNA . It is appreciated that GR584 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR584 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8367] GR584 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM53 PRECURSOR and GAM442 PRE-

CURSOR, each of which GAM precursor RNAs being a hair-pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8368] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM53 RNA and GAM442 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8369] GAM53 RNA binds complimentarily to a target binding site located in an untranslated region of GAM53 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 53A, thereby inhibiting translation of GAM53 TARGET RNA into GAM53 TARGET PROTEIN, both of Fig. 53A.

[8370] GAM442 RNA binds complimentarily to a target binding site located in an untranslated region of GAM442 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 442A, thereby inhibiting translation of GAM442 TARGET RNA into GAM442 TARGET PROTEIN, both of Fig. 442A.

[8371] It is appreciated that specific functions, and accordingly

utilities, of GR584 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR584 GENE: GAM53 TARGET PROTEIN and GAM442 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 53D and 442D

[8372] Reference is now made to Fig. 585, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 585(GR585) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8373] GR585 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR585 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8374] GR585 GENE encodes GR585 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8375] GR585 PRECURSOR RNA folds spatially, forming GR585 FOLDED PRECURSOR RNA . It is appreciated that GR585

FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR585 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8376] GR585 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM44 PRECURSOR and GAM403 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8377] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM44 RNA and GAM403 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8378] GAM44 RNA binds complimentarily to a target binding site located in an untranslated region of GAM44 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING

SITE III of Fig. 44A, thereby inhibiting translation of GAM44 TARGET RNA into GAM44 TARGET PROTEIN, both of Fig. 44A.

[8379] GAM403 RNA binds complimentarily to a target binding site located in an untranslated region of GAM403 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 403A, thereby inhibiting translation of GAM403 TARGET RNA into GAM403 TARGET PROTEIN, both of Fig. 403A.

[8380] It is appreciated that specific functions, and accordingly utilities, of GR585 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR585 GENE: GAM44 TARGET PROTEIN and GAM403 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 44D and 403D

[8381] Reference is now made to Fig. 586, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 586(GR586) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn

modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8382] GR586 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR586 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8383] GR586 GENE encodes GR586 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8384] GR586 PRECURSOR RNA folds spatially, forming GR586 FOLDED PRECURSOR RNA . It is appreciated that GR586 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR586 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8385] GR586 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM110 PRECURSOR and GAM207 PRECURSOR, each of which GAM precursor RNAs being a hair-

pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8386] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM110 RNA and GAM207 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8387] GAM110 RNA binds complimentarily to a target binding site located in an untranslated region of GAM110 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 110A, thereby inhibiting translation of GAM110 TARGET RNA into GAM110 TARGET PROTEIN, both of Fig. 110A.

[8388] GAM207 RNA binds complimentarily to a target binding site located in an untranslated region of GAM207 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 207A, thereby inhibiting translation of GAM207 TARGET RNA into GAM207 TARGET PROTEIN, both of Fig. 207A.

[8389] It is appreciated that specific functions, and accordingly utilities, of GR586 GENE correlate with, and may be de-

duced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR586 GENE: GAM110 TARGET PROTEIN and GAM207 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 110D and 207D

[8390] Reference is now made to Fig. 587, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 587(GR587) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8391] GR587 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR587 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8392] GR587 GENE encodes GR587 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8393] GR587 PRECURSOR RNA folds spatially, forming GR587 FOLDED PRECURSOR RNA . It is appreciated that GR587 FOLDED PRECURSOR RNA comprises a plurality of what is

known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR587 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8394] GR587 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM109 PRECURSOR, GAM215 PRECURSOR and GAM418 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8395] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM109 RNA, GAM215 RNA and GAM418 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8396] GAM109 RNA binds complimentarily to a target binding site located in an untranslated region of GAM109 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 109A, thereby inhibiting transla-

tion of GAM109 TARGET RNA into GAM109 TARGET PROTEIN, both of Fig. 109A.

[8397] GAM215 RNA binds complimentarily to a target binding site located in an untranslated region of GAM215 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 215A, thereby inhibiting translation of GAM215 TARGET RNA into GAM215 TARGET PROTEIN, both of Fig. 215A.

[8398] GAM418 RNA binds complimentarily to a target binding site located in an untranslated region of GAM418 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 418A, thereby inhibiting translation of GAM418 TARGET RNA into GAM418 TARGET PROTEIN, both of Fig. 418A.

[8399] It is appreciated that specific functions, and accordingly utilities, of GR587 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR587 GENE: GAM109 TARGET PROTEIN, GAM215 TARGET PROTEIN and GAM418 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with ref-

erence to Figs. 109D, 215D and 418D

[8400] Reference is now made to Fig. 588, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 588(GR588) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8401] GR588 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR588 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8402] GR588 GENE encodes GR588 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8403] GR588 PRECURSOR RNA folds spatially, forming GR588 FOLDED PRECURSOR RNA . It is appreciated that GR588 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR588 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-re-

versed sequence of the second half thereof, as is well known in the art.

[8404] GR588 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM120 PRECURSOR and GAM205 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8405] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM120 RNA and GAM205 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8406] GAM120 RNA binds complimentarily to a target binding site located in an untranslated region of GAM120 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 120A, thereby inhibiting translation of GAM120 TARGET RNA into GAM120 TARGET PROTEIN, both of Fig. 120A.

[8407] GAM205 RNA binds complimentarily to a target binding site located in an untranslated region of GAM205 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 205A, thereby inhibiting translation of GAM205 TARGET RNA into GAM205 TARGET PROTEIN, both of Fig. 205A.

[8408] It is appreciated that specific functions, and accordingly utilities, of GR588 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR588 GENE: GAM120 TARGET PROTEIN and GAM205 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 120D and 205D

[8409] Reference is now made to Fig. 589, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 589(GR589) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8410] GR589 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR589 GENE was detected is described hereinabove with

reference to Figs. 6-15.

[8411] GR589 GENE encodes GR589 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8412] GR589 PRECURSOR RNA folds spatially, forming GR589 FOLDED PRECURSOR RNA . It is appreciated that GR589 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR589 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8413] GR589 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM31 PRECURSOR, GAM78 PRECURSOR and GAM177 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8414] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM31 RNA, GAM78 RNA and GAM177 RNA respectively, each of which

GAM RNAs corresponding to GAM RNA of Fig. 8.

[8415] GAM31 RNA binds complimentarily to a target binding site located in an untranslated region of GAM31 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 31A, thereby inhibiting translation of GAM31 TARGET RNA into GAM31 TARGET PROTEIN, both of Fig. 31A.

[8416] GAM78 RNA binds complimentarily to a target binding site located in an untranslated region of GAM78 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 78A, thereby inhibiting translation of GAM78 TARGET RNA into GAM78 TARGET PROTEIN, both of Fig. 78A.

[8417] GAM177 RNA binds complimentarily to a target binding site located in an untranslated region of GAM177 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 177A, thereby inhibiting translation of GAM177 TARGET RNA into GAM177 TARGET PROTEIN, both of Fig. 177A.

[8418] It is appreciated that specific functions, and accordingly

utilities, of GR589 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR589 GENE: GAM31 TARGET PROTEIN, GAM78 TARGET PROTEIN and GAM177 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 31D, 78D and 177D

[8419] Reference is now made to Fig. 590, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 590(GR590) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8420] GR590 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR590 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8421] GR590 GENE encodes GR590 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8422] GR590 PRECURSOR RNA folds spatially, forming GR590 FOLDED PRECURSOR RNA . It is appreciated that GR590

FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR590 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8423] GR590 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM258 PRECURSOR, GAM439 PRECURSOR and GAM537 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8424] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM258 RNA, GAM439 RNA and GAM537 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8425] GAM258 RNA binds complimentarily to a target binding site located in an untranslated region of GAM258 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 258A, thereby inhibiting translation of GAM258 TARGET RNA into GAM258 TARGET PROTEIN, both of Fig. 258A.

[8426] GAM439 RNA binds complimentarily to a target binding site located in an untranslated region of GAM439 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 439A, thereby inhibiting translation of GAM439 TARGET RNA into GAM439 TARGET PROTEIN, both of Fig. 439A.

[8427] GAM537 RNA binds complimentarily to a target binding site located in an untranslated region of GAM537 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 537A, thereby inhibiting translation of GAM537 TARGET RNA into GAM537 TARGET PROTEIN, both of Fig. 537A.

[8428] It is appreciated that specific functions, and accordingly utilities, of GR590 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR590 GENE: GAM258 TARGET PROTEIN, GAM439 TARGET PROTEIN and GAM537 TARGET PROTEIN. The function

of these target genes is elaborated hereinabove with reference to Figs. 258D, 439D and 537D

[8429] Reference is now made to Fig. 591, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 591(GR591) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8430] GR591 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR591 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8431] GR591 GENE encodes GR591 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8432] GR591 PRECURSOR RNA folds spatially, forming GR591 FOLDED PRECURSOR RNA . It is appreciated that GR591 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR591 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nu-

cleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8433] GR591 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM209 PRECURSOR and GAM525 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8434] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM209 RNA and GAM525 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8435] GAM209 RNA binds complimentarily to a target binding site located in an untranslated region of GAM209 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 209A, thereby inhibiting translation of GAM209 TARGET RNA into GAM209 TARGET PROTEIN, both of Fig. 209A.

[8436] GAM525 RNA binds complimentarily to a target binding site located in an untranslated region of GAM525 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 525A, thereby inhibiting translation of GAM525 TARGET RNA into GAM525 TARGET PROTEIN, both of Fig. 525A.

[8437] It is appreciated that specific functions, and accordingly utilities, of GR591 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR591 GENE: GAM209 TARGET PROTEIN and GAM525 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 209D and 525D

[8438] Reference is now made to Fig. 592, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 592(GR592) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8439] GR592 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which

GR592 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8440] GR592 GENE encodes GR592 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8441] GR592 PRECURSOR RNA folds spatially, forming GR592 FOLDED PRECURSOR RNA . It is appreciated that GR592 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR592 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8442] GR592 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 4 separate GAM precursor RNAs, GAM27 PRECURSOR, GAM423 PRECURSOR, GAM449 PRECURSOR and GAM459 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8443] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM27 RNA, GAM423 RNA, GAM449 RNA and GAM459 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8444] GAM27 RNA binds complimentarily to a target binding site located in an untranslated region of GAM27 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 27A, thereby inhibiting translation of GAM27 TARGET RNA into GAM27 TARGET PROTEIN, both of Fig. 27A.

[8445] GAM423 RNA binds complimentarily to a target binding site located in an untranslated region of GAM423 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 423A, thereby inhibiting translation of GAM423 TARGET RNA into GAM423 TARGET PROTEIN, both of Fig. 423A.

[8446] GAM449 RNA binds complimentarily to a target binding site located in an untranslated region of GAM449 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 449A, thereby inhibiting transla-

tion of GAM449 TARGET RNA into GAM449 TARGET PROTEIN, both of Fig. 449A.

[8447] GAM459 RNA binds complimentarily to a target binding site located in an untranslated region of GAM459 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 459A, thereby inhibiting translation of GAM459 TARGET RNA into GAM459 TARGET PROTEIN, both of Fig. 459A.

[8448] It is appreciated that specific functions, and accordingly utilities, of GR592 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR592 GENE: GAM27 TARGET PROTEIN, GAM423 TARGET PROTEIN, GAM449 TARGET PROTEIN and GAM459 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 27D, 423D, 449D and 459D

[8449] Reference is now made to Fig. 593, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 593(GR593) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn

modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8450] GR593 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR593 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8451] GR593 GENE encodes GR593 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8452] GR593 PRECURSOR RNA folds spatially, forming GR593 FOLDED PRECURSOR RNA . It is appreciated that GR593 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR593 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8453] GR593 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM32 PRECURSOR and GAM359 PRECURSOR, each of which GAM precursor RNAs being a hair-

pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8454] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM32 RNA and GAM359 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8455] GAM32 RNA binds complimentarily to a target binding site located in an untranslated region of GAM32 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 32A, thereby inhibiting translation of GAM32 TARGET RNA into GAM32 TARGET PROTEIN, both of Fig. 32A.

[8456] GAM359 RNA binds complimentarily to a target binding site located in an untranslated region of GAM359 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 359A, thereby inhibiting translation of GAM359 TARGET RNA into GAM359 TARGET PROTEIN, both of Fig. 359A.

[8457] It is appreciated that specific functions, and accordingly utilities, of GR593 GENE correlate with, and may be de-

duced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR593 GENE: GAM32 TARGET PROTEIN and GAM359 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 32D and 359D

[8458] Reference is now made to Fig. 594, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 594(GR594) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8459] GR594 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR594 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8460] GR594 GENE encodes GR594 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8461] GR594 PRECURSOR RNA folds spatially, forming GR594 FOLDED PRECURSOR RNA . It is appreciated that GR594 FOLDED PRECURSOR RNA comprises a plurality of what is

known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR594 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8462] GR594 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 4 separate GAM precursor RNAs, GAM285 PRECURSOR, GAM326 PRECURSOR, GAM436 PRECURSOR and GAM498 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8463] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM285 RNA, GAM326 RNA, GAM436 RNA and GAM498 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8464] GAM285 RNA binds complimentarily to a target binding site located in an untranslated region of GAM285 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 285A, thereby inhibiting translation of GAM285 TARGET RNA into GAM285 TARGET PROTEIN, both of Fig. 285A.

[8465] GAM326 RNA binds complimentarily to a target binding site located in an untranslated region of GAM326 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 326A, thereby inhibiting translation of GAM326 TARGET RNA into GAM326 TARGET PROTEIN, both of Fig. 326A.

[8466] GAM436 RNA binds complimentarily to a target binding site located in an untranslated region of GAM436 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 436A, thereby inhibiting translation of GAM436 TARGET RNA into GAM436 TARGET PROTEIN, both of Fig. 436A.

[8467] GAM498 RNA binds complimentarily to a target binding site located in an untranslated region of GAM498 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 498A, thereby inhibiting transla-

tion of GAM498 TARGET RNA into GAM498 TARGET PROTEIN, both of Fig. 498A.

[8468] It is appreciated that specific functions, and accordingly utilities, of GR594 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR594 GENE: GAM285 TARGET PROTEIN, GAM326 TARGET PROTEIN, GAM436 TARGET PROTEIN and GAM498 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 285D, 326D, 436D and 498D

[8469] Reference is now made to Fig. 595, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 595(GR595) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8470] GR595 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR595 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8471] GR595 GENE encodes GR595 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8472] GR595 PRECURSOR RNA folds spatially, forming GR595 FOLDED PRECURSOR RNA . It is appreciated that GR595 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR595 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8473] GR595 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM101 PRECURSOR, GAM125 PRECURSOR and GAM183 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8474] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM101 RNA, GAM125 RNA and GAM183 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8475] GAM101 RNA binds complimentarily to a target binding site located in an untranslated region of GAM101 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 101A, thereby inhibiting translation of GAM101 TARGET RNA into GAM101 TARGET PROTEIN, both of Fig. 101A.

[8476] GAM125 RNA binds complimentarily to a target binding site located in an untranslated region of GAM125 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 125A, thereby inhibiting translation of GAM125 TARGET RNA into GAM125 TARGET PROTEIN, both of Fig. 125A.

[8477] GAM183 RNA binds complimentarily to a target binding site located in an untranslated region of GAM183 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 183A, thereby inhibiting translation of GAM183 TARGET RNA into GAM183 TARGET PROTEIN, both of Fig. 183A.

[8478] It is appreciated that specific functions, and accordingly utilities, of GR595 GENE correlate with, and may be de-

duced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR595 GENE: GAM101 TARGET PROTEIN, GAM125 TARGET PROTEIN and GAM183 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 101D, 125D and 183D

[8479] Reference is now made to Fig. 596, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 596(GR596) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8480] GR596 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR596 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8481] GR596 GENE encodes GR596 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8482] GR596 PRECURSOR RNA folds spatially, forming GR596 FOLDED PRECURSOR RNA . It is appreciated that GR596 FOLDED PRECURSOR RNA comprises a plurality of what is

known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR596 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8483] GR596 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8484] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8485] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting transla-

tion of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8486] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8487] It is appreciated that specific functions, and accordingly utilities, of GR596 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR596 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8488] Reference is now made to Fig. 597, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 597(GR597) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the

function and utility of which at least one target gene is known in the art.

[8489] GR597 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR597 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8490] GR597 GENE encodes GR597 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8491] GR597 PRECURSOR RNA folds spatially, forming GR597 FOLDED PRECURSOR RNA . It is appreciated that GR597 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR597 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8492] GR597 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM155 PRECURSOR and GAM413 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECUR-

SOR RNA of Fig. 8.

[8493] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM155 RNA and GAM413 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8494] GAM155 RNA binds complimentarily to a target binding site located in an untranslated region of GAM155 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 155A, thereby inhibiting translation of GAM155 TARGET RNA into GAM155 TARGET PROTEIN, both of Fig. 155A.

[8495] GAM413 RNA binds complimentarily to a target binding site located in an untranslated region of GAM413 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 413A, thereby inhibiting translation of GAM413 TARGET RNA into GAM413 TARGET PROTEIN, both of Fig. 413A.

[8496] It is appreciated that specific functions, and accordingly utilities, of GR597 GENE correlate with, and may be deduced from, the identity of the target genes, which are in-

hibited by GAM RNAs comprised in the operon-like cluster of GR597 GENE: GAM155 TARGET PROTEIN and GAM413 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 155D and 413D

[8497] Reference is now made to Fig. 598, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 598(GR598) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8498] GR598 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR598 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8499] GR598 GENE encodes GR598 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8500] GR598 PRECURSOR RNA folds spatially, forming GR598 FOLDED PRECURSOR RNA . It is appreciated that GR598 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin

structures are due to the fact that the nucleotide sequence of GR598 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8501] GR598 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM39 PRECURSOR and GAM416 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8502] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM39 RNA and GAM416 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8503] GAM39 RNA binds complimentarily to a target binding site located in an untranslated region of GAM39 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 39A, thereby inhibiting translation of GAM39 TARGET RNA into GAM39 TARGET PROTEIN, both

of Fig. 39A.

[8504] GAM416 RNA binds complimentarily to a target binding site located in an untranslated region of GAM416 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 416A, thereby inhibiting translation of GAM416 TARGET RNA into GAM416 TARGET PROTEIN, both of Fig. 416A.

[8505] It is appreciated that specific functions, and accordingly utilities, of GR598 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR598 GENE: GAM39 TARGET PROTEIN and GAM416 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 39D and 416D

[8506] Reference is now made to Fig. 599, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 599(GR599) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is

known in the art.

[8507] GR599 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR599 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8508] GR599 GENE encodes GR599 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8509] GR599 PRECURSOR RNA folds spatially, forming GR599 FOLDED PRECURSOR RNA . It is appreciated that GR599 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR599 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8510] GR599 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM441 PRECURSOR and GAM527 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8511] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM441 RNA and GAM527 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8512] GAM441 RNA binds complimentarily to a target binding site located in an untranslated region of GAM441 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 441A, thereby inhibiting translation of GAM441 TARGET RNA into GAM441 TARGET PROTEIN, both of Fig. 441A.

[8513] GAM527 RNA binds complimentarily to a target binding site located in an untranslated region of GAM527 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 527A, thereby inhibiting translation of GAM527 TARGET RNA into GAM527 TARGET PROTEIN, both of Fig. 527A.

[8514] It is appreciated that specific functions, and accordingly utilities, of GR599 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR599 GENE: GAM441 TARGET PROTEIN and GAM527 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 441D and 527D

[8515] Reference is now made to Fig. 600, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 600(GR600) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8516] GR600 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR600 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8517] GR600 GENE encodes GR600 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8518] GR600 PRECURSOR RNA folds spatially, forming GR600 FOLDED PRECURSOR RNA . It is appreciated that GR600 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR600 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8519] GR600 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM254 PRECURSOR and GAM495 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8520] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM254 RNA and GAM495 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8521] GAM254 RNA binds complimentarily to a target binding site located in an untranslated region of GAM254 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 254A, thereby inhibiting translation of GAM254 TARGET RNA into GAM254 TARGET PROTEIN, both of Fig. 254A.

[8522] GAM495 RNA binds complimentarily to a target binding site located in an untranslated region of GAM495 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 495A, thereby inhibiting translation of GAM495 TARGET RNA into GAM495 TARGET PROTEIN, both of Fig. 495A.

[8523] It is appreciated that specific functions, and accordingly utilities, of GR600 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR600 GENE: GAM254 TARGET PROTEIN and GAM495 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 254D and 495D

[8524] Reference is now made to Fig. 601, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 601(GR601) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8525] GR601 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR601 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8526] GR601 GENE encodes GR601 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8527] GR601 PRECURSOR RNA folds spatially, forming GR601 FOLDED PRECURSOR RNA . It is appreciated that GR601 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR601 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8528] GR601 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM51 PRECURSOR and GAM298 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8529] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM51 RNA and GAM298 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8530] GAM51 RNA binds complimentarily to a target binding site located in an untranslated region of GAM51 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 51A, thereby inhibiting translation of GAM51 TARGET RNA into GAM51 TARGET PROTEIN, both of Fig. 51A.

[8531] GAM298 RNA binds complimentarily to a target binding site located in an untranslated region of GAM298 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 298A, thereby inhibiting translation of GAM298 TARGET RNA into GAM298 TARGET PROTEIN, both of Fig. 298A.

[8532] It is appreciated that specific functions, and accordingly utilities, of GR601 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR601 GENE: GAM51 TARGET PROTEIN and GAM298

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 51D and 298D

[8533] Reference is now made to Fig. 602, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 602(GR602) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8534] GR602 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR602 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8535] GR602 GENE encodes GR602 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8536] GR602 PRECURSOR RNA folds spatially, forming GR602 FOLDED PRECURSOR RNA . It is appreciated that GR602 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR602 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8537] GR602 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM222 PRECURSOR, GAM341 PRECURSOR and GAM484 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8538] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM222 RNA, GAM341 RNA and GAM484 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8539] GAM222 RNA binds complimentarily to a target binding site located in an untranslated region of GAM222 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 222A, thereby inhibiting translation of GAM222 TARGET RNA into GAM222 TARGET PROTEIN, both of Fig. 222A.

[8540] GAM341 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM341 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 341A, thereby inhibiting translation of GAM341 TARGET RNA into GAM341 TARGET PROTEIN, both of Fig. 341A.

[8541] GAM484 RNA binds complimentarily to a target binding site located in an untranslated region of GAM484 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 484A, thereby inhibiting translation of GAM484 TARGET RNA into GAM484 TARGET PROTEIN, both of Fig. 484A.

[8542] It is appreciated that specific functions, and accordingly utilities, of GR602 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR602 GENE: GAM222 TARGET PROTEIN, GAM341 TARGET PROTEIN and GAM484 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 222D, 341D and 484D

[8543] Reference is now made to Fig. 603, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 603(GR603) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8544] GR603 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR603 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8545] GR603 GENE encodes GR603 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8546] GR603 PRECURSOR RNA folds spatially, forming GR603 FOLDED PRECURSOR RNA . It is appreciated that GR603 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR603 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8547] GR603 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM314 PRECURSOR and GAM433 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8548] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM314 RNA and GAM433 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8549] GAM314 RNA binds complimentarily to a target binding site located in an untranslated region of GAM314 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 314A, thereby inhibiting translation of GAM314 TARGET RNA into GAM314 TARGET PROTEIN, both of Fig. 314A.

[8550] GAM433 RNA binds complimentarily to a target binding site located in an untranslated region of GAM433 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 433A, thereby inhibiting translation of GAM433 TARGET RNA into GAM433 TARGET PRO-

TEIN, both of Fig. 433A.

[8551] It is appreciated that specific functions, and accordingly utilities, of GR603 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR603 GENE: GAM314 TARGET PROTEIN and GAM433 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 314D and 433D

[8552] Reference is now made to Fig. 604, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 604(GR604) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8553] GR604 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR604 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8554] GR604 GENE encodes GR604 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8555] GR604 PRECURSOR RNA folds spatially, forming GR604 FOLDED PRECURSOR RNA . It is appreciated that GR604 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR604 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8556] GR604 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM109 PRECURSOR, GAM215 PRECURSOR and GAM418 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8557] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM109 RNA, GAM215 RNA and GAM418 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8558] GAM109 RNA binds complimentarily to a target binding site located in an untranslated region of GAM109 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 109A, thereby inhibiting translation of GAM109 TARGET RNA into GAM109 TARGET PROTEIN, both of Fig. 109A.

[8559] GAM215 RNA binds complimentarily to a target binding site located in an untranslated region of GAM215 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 215A, thereby inhibiting translation of GAM215 TARGET RNA into GAM215 TARGET PROTEIN, both of Fig. 215A.

[8560] GAM418 RNA binds complimentarily to a target binding site located in an untranslated region of GAM418 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 418A, thereby inhibiting translation of GAM418 TARGET RNA into GAM418 TARGET PROTEIN, both of Fig. 418A.

[8561] It is appreciated that specific functions, and accordingly utilities, of GR604 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR604 GENE: GAM109 TARGET PROTEIN, GAM215 TARGET PROTEIN and GAM418 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 109D, 215D and 418D

[8562] Reference is now made to Fig. 605, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 605(GR605) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8563] GR605 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR605 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8564] GR605 GENE encodes GR605 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8565] GR605 PRECURSOR RNA folds spatially, forming GR605 FOLDED PRECURSOR RNA . It is appreciated that GR605 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR605 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8566] GR605 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM46 PRECURSOR, GAM77 PRECURSOR and GAM382 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8567] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM46 RNA, GAM77 RNA and GAM382 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8568] GAM46 RNA binds complimentarily to a target binding site located in an untranslated region of GAM46 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 46A, thereby inhibiting translation of GAM46 TARGET RNA into GAM46 TARGET PROTEIN, both of Fig. 46A.

[8569] GAM77 RNA binds complimentarily to a target binding site located in an untranslated region of GAM77 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 77A, thereby inhibiting translation of GAM77 TARGET RNA into GAM77 TARGET PROTEIN, both of Fig. 77A.

[8570] GAM382 RNA binds complimentarily to a target binding site located in an untranslated region of GAM382 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 382A, thereby inhibiting translation of GAM382 TARGET RNA into GAM382 TARGET PROTEIN, both of Fig. 382A.

[8571] It is appreciated that specific functions, and accordingly utilities, of GR605 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR605 GENE: GAM46 TARGET PROTEIN, GAM77 TARGET PROTEIN and GAM382 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 46D, 77D and 382D

[8572] Reference is now made to Fig. 606, which is a simplified

diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 606(GR606) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8573] GR606 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR606 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8574] GR606 GENE encodes GR606 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8575] GR606 PRECURSOR RNA folds spatially, forming GR606 FOLDED PRECURSOR RNA . It is appreciated that GR606 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR606 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8576] GR606 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM447 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8577] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM447 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8578] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8579] GAM447 RNA binds complimentarily to a target binding site located in an untranslated region of GAM447 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 447A, thereby inhibiting transla-

tion of GAM447 TARGET RNA into GAM447 TARGET PROTEIN, both of Fig. 447A.

[8580] It is appreciated that specific functions, and accordingly utilities, of GR606 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR606 GENE: GAM218 TARGET PROTEIN and GAM447 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 447D

[8581] Reference is now made to Fig. 607, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 607(GR607) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8582] GR607 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR607 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8583] GR607 GENE encodes GR607 PRECURSOR RNA, an RNA

molecule, typically several hundred nucleotides long.

[8584] GR607 PRECURSOR RNA folds spatially, forming GR607 FOLDED PRECURSOR RNA . It is appreciated that GR607 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR607 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8585] GR607 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM283 PRECURSOR and GAM297 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8586] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM283 RNA and GAM297 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8587] GAM283 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM283 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 283A, thereby inhibiting translation of GAM283 TARGET RNA into GAM283 TARGET PROTEIN, both of Fig. 283A.

[8588] GAM297 RNA binds complimentarily to a target binding site located in an untranslated region of GAM297 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 297A, thereby inhibiting translation of GAM297 TARGET RNA into GAM297 TARGET PROTEIN, both of Fig. 297A.

[8589] It is appreciated that specific functions, and accordingly utilities, of GR607 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR607 GENE: GAM283 TARGET PROTEIN and GAM297 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 283D and 297D

[8590] Reference is now made to Fig. 608, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 608(GR608) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8591] GR608 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR608 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8592] GR608 GENE encodes GR608 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8593] GR608 PRECURSOR RNA folds spatially, forming GR608 FOLDED PRECURSOR RNA . It is appreciated that GR608 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR608 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8594] GR608 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM38 PRECURSOR and GAM333 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8595] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM38 RNA and GAM333 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8596] GAM38 RNA binds complimentarily to a target binding site located in an untranslated region of GAM38 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 38A, thereby inhibiting translation of GAM38 TARGET RNA into GAM38 TARGET PROTEIN, both of Fig. 38A.

[8597] GAM333 RNA binds complimentarily to a target binding site located in an untranslated region of GAM333 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 333A, thereby inhibiting translation of GAM333 TARGET RNA into GAM333 TARGET PRO-

TEIN, both of Fig. 333A.

[8598] It is appreciated that specific functions, and accordingly utilities, of GR608 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR608 GENE: GAM38 TARGET PROTEIN and GAM333 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 38D and 333D

[8599] Reference is now made to Fig. 609, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 609(GR609) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8600] GR609 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR609 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8601] GR609 GENE encodes GR609 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8602] GR609 PRECURSOR RNA folds spatially, forming GR609 FOLDED PRECURSOR RNA . It is appreciated that GR609 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR609 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8603] GR609 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM265 PRECURSOR and GAM276 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8604] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM265 RNA and GAM276 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8605] GAM265 RNA binds complimentarily to a target binding site located in an untranslated region of GAM265 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 265A, thereby inhibiting translation of GAM265 TARGET RNA into GAM265 TARGET PROTEIN, both of Fig. 265A.

[8606] GAM276 RNA binds complimentarily to a target binding site located in an untranslated region of GAM276 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 276A, thereby inhibiting translation of GAM276 TARGET RNA into GAM276 TARGET PROTEIN, both of Fig. 276A.

[8607] It is appreciated that specific functions, and accordingly utilities, of GR609 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR609 GENE: GAM265 TARGET PROTEIN and GAM276 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 265D and 276D

[8608] Reference is now made to Fig. 610, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record

610(GR610) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8609] GR610 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR610 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8610] GR610 GENE encodes GR610 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8611] GR610 PRECURSOR RNA folds spatially, forming GR610 FOLDED PRECURSOR RNA . It is appreciated that GR610 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR610 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8612] GR610 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM

precursor RNAs, GAM251 PRECURSOR, GAM306 PRECURSOR and GAM510 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8613] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM251 RNA, GAM306 RNA and GAM510 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8614] GAM251 RNA binds complimentarily to a target binding site located in an untranslated region of GAM251 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 251A, thereby inhibiting translation of GAM251 TARGET RNA into GAM251 TARGET PROTEIN, both of Fig. 251A.

[8615] GAM306 RNA binds complimentarily to a target binding site located in an untranslated region of GAM306 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 306A, thereby inhibiting translation of GAM306 TARGET RNA into GAM306 TARGET PROTEIN, both of Fig. 306A.

[8616] GAM510 RNA binds complimentarily to a target binding site located in an untranslated region of GAM510 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 510A, thereby inhibiting translation of GAM510 TARGET RNA into GAM510 TARGET PROTEIN, both of Fig. 510A.

[8617] It is appreciated that specific functions, and accordingly utilities, of GR610 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR610 GENE: GAM251 TARGET PROTEIN, GAM306 TARGET PROTEIN and GAM510 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 251D, 306D and 510D

[8618] Reference is now made to Fig. 611, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 611(GR611) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8619] GR611 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR611 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8620] GR611 GENE encodes GR611 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8621] GR611 PRECURSOR RNA folds spatially, forming GR611 FOLDED PRECURSOR RNA . It is appreciated that GR611 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR611 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8622] GR611 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM230 PRECURSOR and GAM307 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8623] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM230 RNA and GAM307 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8624] GAM230 RNA binds complimentarily to a target binding site located in an untranslated region of GAM230 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 230A, thereby inhibiting translation of GAM230 TARGET RNA into GAM230 TARGET PROTEIN, both of Fig. 230A.

[8625] GAM307 RNA binds complimentarily to a target binding site located in an untranslated region of GAM307 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 307A, thereby inhibiting translation of GAM307 TARGET RNA into GAM307 TARGET PROTEIN, both of Fig. 307A.

[8626] It is appreciated that specific functions, and accordingly utilities, of GR611 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR611 GENE: GAM230 TARGET PROTEIN and GAM307

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 230D and 307D

[8627] Reference is now made to Fig. 612, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 612(GR612) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8628] GR612 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR612 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8629] GR612 GENE encodes GR612 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8630] GR612 PRECURSOR RNA folds spatially, forming GR612 FOLDED PRECURSOR RNA . It is appreciated that GR612 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR612 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8631] GR612 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM296 PRECURSOR and GAM303 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8632] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM296 RNA and GAM303 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8633] GAM296 RNA binds complimentarily to a target binding site located in an untranslated region of GAM296 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 296A, thereby inhibiting translation of GAM296 TARGET RNA into GAM296 TARGET PROTEIN, both of Fig. 296A.

[8634] GAM303 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM303 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 303A, thereby inhibiting translation of GAM303 TARGET RNA into GAM303 TARGET PROTEIN, both of Fig. 303A.

[8635] It is appreciated that specific functions, and accordingly utilities, of GR612 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR612 GENE: GAM296 TARGET PROTEIN and GAM303 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 296D and 303D

[8636] Reference is now made to Fig. 613, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 613(GR613) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8637] GR613 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR613 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8638] GR613 GENE encodes GR613 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8639] GR613 PRECURSOR RNA folds spatially, forming GR613 FOLDED PRECURSOR RNA . It is appreciated that GR613 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR613 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8640] GR613 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM199 PRECURSOR, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8641] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM199 RNA, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8642] GAM199 RNA binds complimentarily to a target binding site located in an untranslated region of GAM199 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 199A, thereby inhibiting translation of GAM199 TARGET RNA into GAM199 TARGET PROTEIN, both of Fig. 199A.

[8643] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8644] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PRO-

TEIN, both of Fig. 448A.

[8645] It is appreciated that specific functions, and accordingly utilities, of GR613 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR613 GENE: GAM199 TARGET PROTEIN, GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 199D, 218D and 448D

[8646] Reference is now made to Fig. 614, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 614(GR614) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8647] GR614 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR614 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8648] GR614 GENE encodes GR614 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8649] GR614 PRECURSOR RNA folds spatially, forming GR614 FOLDED PRECURSOR RNA . It is appreciated that GR614 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR614 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8650] GR614 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM526 PRECURSOR and GAM541 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8651] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM526 RNA and GAM541 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8652] GAM526 RNA binds complimentarily to a target binding site located in an untranslated region of GAM526 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 526A, thereby inhibiting translation of GAM526 TARGET RNA into GAM526 TARGET PROTEIN, both of Fig. 526A.

[8653] GAM541 RNA binds complimentarily to a target binding site located in an untranslated region of GAM541 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 541A, thereby inhibiting translation of GAM541 TARGET RNA into GAM541 TARGET PROTEIN, both of Fig. 541A.

[8654] It is appreciated that specific functions, and accordingly utilities, of GR614 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR614 GENE: GAM526 TARGET PROTEIN and GAM541 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 526D and 541D

[8655] Reference is now made to Fig. 615, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record

615(GR615) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8656] GR615 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR615 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8657] GR615 GENE encodes GR615 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8658] GR615 PRECURSOR RNA folds spatially, forming GR615 FOLDED PRECURSOR RNA . It is appreciated that GR615 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR615 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8659] GR615 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM

precursor RNAs, GAM113 PRECURSOR and GAM221 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8660] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM113 RNA and GAM221 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8661] GAM113 RNA binds complimentarily to a target binding site located in an untranslated region of GAM113 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 113A, thereby inhibiting translation of GAM113 TARGET RNA into GAM113 TARGET PROTEIN, both of Fig. 113A.

[8662] GAM221 RNA binds complimentarily to a target binding site located in an untranslated region of GAM221 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 221A, thereby inhibiting translation of GAM221 TARGET RNA into GAM221 TARGET PROTEIN, both of Fig. 221A.

[8663] It is appreciated that specific functions, and accordingly utilities, of GR615 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR615 GENE: GAM113 TARGET PROTEIN and GAM221 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 113D and 221D

[8664] Reference is now made to Fig. 616, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 616(GR616) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8665] GR616 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR616 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8666] GR616 GENE encodes GR616 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8667] GR616 PRECURSOR RNA folds spatially, forming GR616

FOLDED PRECURSOR RNA . It is appreciated that GR616 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR616 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8668] GR616 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM94 PRECURSOR and GAM175 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8669] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM94 RNA and GAM175 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8670] GAM94 RNA binds complimentarily to a target binding site located in an untranslated region of GAM94 TARGET RNA, which target binding site corresponds to a target binding

site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 94A, thereby inhibiting translation of GAM94 TARGET RNA into GAM94 TARGET PROTEIN, both of Fig. 94A.

[8671] GAM175 RNA binds complimentarily to a target binding site located in an untranslated region of GAM175 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 175A, thereby inhibiting translation of GAM175 TARGET RNA into GAM175 TARGET PROTEIN, both of Fig. 175A.

[8672] It is appreciated that specific functions, and accordingly utilities, of GR616 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR616 GENE: GAM94 TARGET PROTEIN and GAM175 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 94D and 175D

[8673] Reference is now made to Fig. 617, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 617(GR617) gene, which encodes an operon-like cluster

of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8674] GR617 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR617 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8675] GR617 GENE encodes GR617 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8676] GR617 PRECURSOR RNA folds spatially, forming GR617 FOLDED PRECURSOR RNA . It is appreciated that GR617 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR617 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8677] GR617 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM28 PRECURSOR and GAM274 PRE-

CURSOR, each of which GAM precursor RNAs being a hair-pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8678] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM28 RNA and GAM274 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8679] GAM28 RNA binds complimentarily to a target binding site located in an untranslated region of GAM28 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 28A, thereby inhibiting translation of GAM28 TARGET RNA into GAM28 TARGET PROTEIN, both of Fig. 28A.

[8680] GAM274 RNA binds complimentarily to a target binding site located in an untranslated region of GAM274 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 274A, thereby inhibiting translation of GAM274 TARGET RNA into GAM274 TARGET PROTEIN, both of Fig. 274A.

[8681] It is appreciated that specific functions, and accordingly

utilities, of GR617 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR617 GENE: GAM28 TARGET PROTEIN and GAM274 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 28D and 274D

[8682] Reference is now made to Fig. 618, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 618(GR618) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8683] GR618 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR618 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8684] GR618 GENE encodes GR618 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8685] GR618 PRECURSOR RNA folds spatially, forming GR618 FOLDED PRECURSOR RNA . It is appreciated that GR618

FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR618 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8686] GR618 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM174 PRECURSOR and GAM259 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8687] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM174 RNA and GAM259 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8688] GAM174 RNA binds complimentarily to a target binding site located in an untranslated region of GAM174 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 174A, thereby inhibiting translation of GAM174 TARGET RNA into GAM174 TARGET PROTEIN, both of Fig. 174A.

[8689] GAM259 RNA binds complimentarily to a target binding site located in an untranslated region of GAM259 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 259A, thereby inhibiting translation of GAM259 TARGET RNA into GAM259 TARGET PROTEIN, both of Fig. 259A.

[8690] It is appreciated that specific functions, and accordingly utilities, of GR618 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR618 GENE: GAM174 TARGET PROTEIN and GAM259 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 174D and 259D

[8691] Reference is now made to Fig. 619, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 619(GR619) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn

modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8692] GR619 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR619 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8693] GR619 GENE encodes GR619 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8694] GR619 PRECURSOR RNA folds spatially, forming GR619 FOLDED PRECURSOR RNA . It is appreciated that GR619 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR619 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8695] GR619 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM526 PRECURSOR and GAM541 PRECURSOR, each of which GAM precursor RNAs being a hair-

pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8696] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM526 RNA and GAM541 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8697] GAM526 RNA binds complimentarily to a target binding site located in an untranslated region of GAM526 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 526A, thereby inhibiting translation of GAM526 TARGET RNA into GAM526 TARGET PROTEIN, both of Fig. 526A.

[8698] GAM541 RNA binds complimentarily to a target binding site located in an untranslated region of GAM541 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 541A, thereby inhibiting translation of GAM541 TARGET RNA into GAM541 TARGET PROTEIN, both of Fig. 541A.

[8699] It is appreciated that specific functions, and accordingly utilities, of GR619 GENE correlate with, and may be de-

duced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR619 GENE: GAM526 TARGET PROTEIN and GAM541 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 526D and 541D

[8700] Reference is now made to Fig. 620, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 620(GR620) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8701] GR620 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR620 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8702] GR620 GENE encodes GR620 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8703] GR620 PRECURSOR RNA folds spatially, forming GR620 FOLDED PRECURSOR RNA . It is appreciated that GR620 FOLDED PRECURSOR RNA comprises a plurality of what is

known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR620 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8704] GR620 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM172 PRECURSOR and GAM462 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8705] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM172 RNA and GAM462 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8706] GAM172 RNA binds complimentarily to a target binding site located in an untranslated region of GAM172 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 172A, thereby inhibiting transla-

tion of GAM172 TARGET RNA into GAM172 TARGET PROTEIN, both of Fig. 172A.

[8707] GAM462 RNA binds complimentarily to a target binding site located in an untranslated region of GAM462 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 462A, thereby inhibiting translation of GAM462 TARGET RNA into GAM462 TARGET PROTEIN, both of Fig. 462A.

[8708] It is appreciated that specific functions, and accordingly utilities, of GR620 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR620 GENE: GAM172 TARGET PROTEIN and GAM462 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 172D and 462D

[8709] Reference is now made to Fig. 621, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 621(GR621) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the

function and utility of which at least one target gene is known in the art.

[8710] GR621 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR621 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8711] GR621 GENE encodes GR621 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8712] GR621 PRECURSOR RNA folds spatially, forming GR621 FOLDED PRECURSOR RNA . It is appreciated that GR621 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR621 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8713] GR621 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM391 PRECURSOR and GAM500 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECUR-

SOR RNA of Fig. 8.

[8714] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM391 RNA and GAM500 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8715] GAM391 RNA binds complimentarily to a target binding site located in an untranslated region of GAM391 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 391A, thereby inhibiting translation of GAM391 TARGET RNA into GAM391 TARGET PROTEIN, both of Fig. 391A.

[8716] GAM500 RNA binds complimentarily to a target binding site located in an untranslated region of GAM500 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 500A, thereby inhibiting translation of GAM500 TARGET RNA into GAM500 TARGET PROTEIN, both of Fig. 500A.

[8717] It is appreciated that specific functions, and accordingly utilities, of GR621 GENE correlate with, and may be deduced from, the identity of the target genes, which are in-

hibited by GAM RNAs comprised in the operon-like cluster of GR621 GENE: GAM391 TARGET PROTEIN and GAM500 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 391D and 500D

[8718] Reference is now made to Fig. 622, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 622(GR622) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8719] GR622 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR622 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8720] GR622 GENE encodes GR622 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8721] GR622 PRECURSOR RNA folds spatially, forming GR622 FOLDED PRECURSOR RNA . It is appreciated that GR622 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin

structures are due to the fact that the nucleotide sequence of GR622 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8722] GR622 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM139 PRECURSOR, GAM159 PRECURSOR and GAM377 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8723] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM139 RNA, GAM159 RNA and GAM377 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8724] GAM139 RNA binds complimentarily to a target binding site located in an untranslated region of GAM139 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 139A, thereby inhibiting translation of GAM139 TARGET RNA into GAM139 TARGET PRO-

TEIN, both of Fig. 139A.

[8725] GAM159 RNA binds complimentarily to a target binding site located in an untranslated region of GAM159 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 159A, thereby inhibiting translation of GAM159 TARGET RNA into GAM159 TARGET PROTEIN, both of Fig. 159A.

[8726] GAM377 RNA binds complimentarily to a target binding site located in an untranslated region of GAM377 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 377A, thereby inhibiting translation of GAM377 TARGET RNA into GAM377 TARGET PROTEIN, both of Fig. 377A.

[8727] It is appreciated that specific functions, and accordingly utilities, of GR622 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR622 GENE: GAM139 TARGET PROTEIN, GAM159 TARGET PROTEIN and GAM377 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 139D, 159D and 377D

[8728] Reference is now made to Fig. 623, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 623(GR623) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8729] GR623 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR623 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8730] GR623 GENE encodes GR623 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8731] GR623 PRECURSOR RNA folds spatially, forming GR623 FOLDED PRECURSOR RNA . It is appreciated that GR623 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR623 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well

known in the art.

[8732] GR623 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM236 PRECURSOR and GAM360 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8733] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM236 RNA and GAM360 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8734] GAM236 RNA binds complimentarily to a target binding site located in an untranslated region of GAM236 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 236A, thereby inhibiting translation of GAM236 TARGET RNA into GAM236 TARGET PROTEIN, both of Fig. 236A.

[8735] GAM360 RNA binds complimentarily to a target binding site located in an untranslated region of GAM360 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 360A, thereby inhibiting translation of GAM360 TARGET RNA into GAM360 TARGET PROTEIN, both of Fig. 360A.

[8736] It is appreciated that specific functions, and accordingly utilities, of GR623 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR623 GENE: GAM236 TARGET PROTEIN and GAM360 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 236D and 360D

[8737] Reference is now made to Fig. 624, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 624(GR624) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8738] GR624 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR624 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8739] GR624 GENE encodes GR624 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8740] GR624 PRECURSOR RNA folds spatially, forming GR624 FOLDED PRECURSOR RNA . It is appreciated that GR624 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR624 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8741] GR624 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM66 PRECURSOR and GAM474 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8742] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM66 RNA and GAM474 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8743] GAM66 RNA binds complimentarily to a target binding site located in an untranslated region of GAM66 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 66A, thereby inhibiting translation of GAM66 TARGET RNA into GAM66 TARGET PROTEIN, both of Fig. 66A.

[8744] GAM474 RNA binds complimentarily to a target binding site located in an untranslated region of GAM474 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 474A, thereby inhibiting translation of GAM474 TARGET RNA into GAM474 TARGET PROTEIN, both of Fig. 474A.

[8745] It is appreciated that specific functions, and accordingly utilities, of GR624 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR624 GENE: GAM66 TARGET PROTEIN and GAM474 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 66D and 474D

[8746] Reference is now made to Fig. 625, which is a simplified

diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 625(GR625) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8747] GR625 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR625 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8748] GR625 GENE encodes GR625 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8749] GR625 PRECURSOR RNA folds spatially, forming GR625 FOLDED PRECURSOR RNA . It is appreciated that GR625 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR625 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8750] GR625 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM291 PRECURSOR and GAM419 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8751] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM291 RNA and GAM419 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8752] GAM291 RNA binds complimentarily to a target binding site located in an untranslated region of GAM291 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 291A, thereby inhibiting translation of GAM291 TARGET RNA into GAM291 TARGET PROTEIN, both of Fig. 291A.

[8753] GAM419 RNA binds complimentarily to a target binding site located in an untranslated region of GAM419 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 419A, thereby inhibiting transla-

tion of GAM419 TARGET RNA into GAM419 TARGET PROTEIN, both of Fig. 419A.

[8754] It is appreciated that specific functions, and accordingly utilities, of GR625 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR625 GENE: GAM291 TARGET PROTEIN and GAM419 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 291D and 419D

[8755] Reference is now made to Fig. 626, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 626(GR626) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8756] GR626 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR626 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8757] GR626 GENE encodes GR626 PRECURSOR RNA, an RNA

molecule, typically several hundred nucleotides long.

[8758] GR626 PRECURSOR RNA folds spatially, forming GR626 FOLDED PRECURSOR RNA . It is appreciated that GR626 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR626 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8759] GR626 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM30 PRECURSOR and GAM227 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8760] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM30 RNA and GAM227 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8761] GAM30 RNA binds complimentarily to a target binding site

located in an untranslated region of GAM30 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 30A, thereby inhibiting translation of GAM30 TARGET RNA into GAM30 TARGET PROTEIN, both of Fig. 30A.

[8762] GAM227 RNA binds complimentarily to a target binding site located in an untranslated region of GAM227 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 227A, thereby inhibiting translation of GAM227 TARGET RNA into GAM227 TARGET PROTEIN, both of Fig. 227A.

[8763] It is appreciated that specific functions, and accordingly utilities, of GR626 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR626 GENE: GAM30 TARGET PROTEIN and GAM227 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 30D and 227D

[8764] Reference is now made to Fig. 627, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 627(GR627) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8765] GR627 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR627 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8766] GR627 GENE encodes GR627 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8767] GR627 PRECURSOR RNA folds spatially, forming GR627 FOLDED PRECURSOR RNA . It is appreciated that GR627 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR627 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8768] GR627 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM196 PRECURSOR, GAM411 PRECURSOR and GAM468 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8769] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM196 RNA, GAM411 RNA and GAM468 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8770] GAM196 RNA binds complimentarily to a target binding site located in an untranslated region of GAM196 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 196A, thereby inhibiting translation of GAM196 TARGET RNA into GAM196 TARGET PROTEIN, both of Fig. 196A.

[8771] GAM411 RNA binds complimentarily to a target binding site located in an untranslated region of GAM411 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 411A, thereby inhibiting translation of GAM411 TARGET RNA into GAM411 TARGET PRO-

TEIN, both of Fig. 411A.

[8772] GAM468 RNA binds complimentarily to a target binding site located in an untranslated region of GAM468 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 468A, thereby inhibiting translation of GAM468 TARGET RNA into GAM468 TARGET PROTEIN, both of Fig. 468A.

[8773] It is appreciated that specific functions, and accordingly utilities, of GR627 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR627 GENE: GAM196 TARGET PROTEIN, GAM411 TARGET PROTEIN and GAM468 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 196D, 411D and 468D

[8774] Reference is now made to Fig. 628, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 628(GR628) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is

known in the art.

[8775] GR628 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR628 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8776] GR628 GENE encodes GR628 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8777] GR628 PRECURSOR RNA folds spatially, forming GR628 FOLDED PRECURSOR RNA . It is appreciated that GR628 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR628 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8778] GR628 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM146 PRECURSOR and GAM410 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8779] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM146 RNA and GAM410 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8780] GAM146 RNA binds complimentarily to a target binding site located in an untranslated region of GAM146 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 146A, thereby inhibiting translation of GAM146 TARGET RNA into GAM146 TARGET PROTEIN, both of Fig. 146A.

[8781] GAM410 RNA binds complimentarily to a target binding site located in an untranslated region of GAM410 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 410A, thereby inhibiting translation of GAM410 TARGET RNA into GAM410 TARGET PROTEIN, both of Fig. 410A.

[8782] It is appreciated that specific functions, and accordingly utilities, of GR628 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR628 GENE: GAM146 TARGET PROTEIN and GAM410 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 146D and 410D

[8783] Reference is now made to Fig. 629, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 629(GR629) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8784] GR629 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR629 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8785] GR629 GENE encodes GR629 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8786] GR629 PRECURSOR RNA folds spatially, forming GR629 FOLDED PRECURSOR RNA . It is appreciated that GR629 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR629 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8787] GR629 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM223 PRECURSOR and GAM356 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8788] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM223 RNA and GAM356 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8789] GAM223 RNA binds complimentarily to a target binding site located in an untranslated region of GAM223 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 223A, thereby inhibiting translation of GAM223 TARGET RNA into GAM223 TARGET PROTEIN, both of Fig. 223A.

[8790] GAM356 RNA binds complimentarily to a target binding site located in an untranslated region of GAM356 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 356A, thereby inhibiting translation of GAM356 TARGET RNA into GAM356 TARGET PROTEIN, both of Fig. 356A.

[8791] It is appreciated that specific functions, and accordingly utilities, of GR629 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR629 GENE: GAM223 TARGET PROTEIN and GAM356 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 223D and 356D

[8792] Reference is now made to Fig. 630, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 630(GR630) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8793] GR630 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR630 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8794] GR630 GENE encodes GR630 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8795] GR630 PRECURSOR RNA folds spatially, forming GR630 FOLDED PRECURSOR RNA . It is appreciated that GR630 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR630 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8796] GR630 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM173 PRECURSOR and GAM351 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8797] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM173 RNA and GAM351 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8798] GAM173 RNA binds complimentarily to a target binding site located in an untranslated region of GAM173 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 173A, thereby inhibiting translation of GAM173 TARGET RNA into GAM173 TARGET PROTEIN, both of Fig. 173A.

[8799] GAM351 RNA binds complimentarily to a target binding site located in an untranslated region of GAM351 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 351A, thereby inhibiting translation of GAM351 TARGET RNA into GAM351 TARGET PROTEIN, both of Fig. 351A.

[8800] It is appreciated that specific functions, and accordingly utilities, of GR630 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR630 GENE: GAM173 TARGET PROTEIN and GAM351

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 173D and 351D

[8801] Reference is now made to Fig. 631, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 631(GR631) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8802] GR631 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR631 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8803] GR631 GENE encodes GR631 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8804] GR631 PRECURSOR RNA folds spatially, forming GR631 FOLDED PRECURSOR RNA . It is appreciated that GR631 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR631 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8805] GR631 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8806] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8807] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8808] GAM448 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8809] It is appreciated that specific functions, and accordingly utilities, of GR631 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR631 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8810] Reference is now made to Fig. 632, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 632(GR632) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8811] GR632 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR632 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8812] GR632 GENE encodes GR632 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8813] GR632 PRECURSOR RNA folds spatially, forming GR632 FOLDED PRECURSOR RNA . It is appreciated that GR632 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR632 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8814] GR632 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM104 PRECURSOR, GAM162 PRECURSOR and GAM497 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8815] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM104 RNA, GAM162 RNA and GAM497 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8816] GAM104 RNA binds complimentarily to a target binding site located in an untranslated region of GAM104 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 104A, thereby inhibiting translation of GAM104 TARGET RNA into GAM104 TARGET PROTEIN, both of Fig. 104A.

[8817] GAM162 RNA binds complimentarily to a target binding site located in an untranslated region of GAM162 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 162A, thereby inhibiting translation of GAM162 TARGET RNA into GAM162 TARGET PROTEIN, both of Fig. 162A.

[8818] GAM497 RNA binds complimentarily to a target binding site located in an untranslated region of GAM497 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 497A, thereby inhibiting translation of GAM497 TARGET RNA into GAM497 TARGET PRO-

TEIN, both of Fig. 497A.

[8819] It is appreciated that specific functions, and accordingly utilities, of GR632 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR632 GENE: GAM104 TARGET PROTEIN, GAM162 TARGET PROTEIN and GAM497 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 104D, 162D and 497D

[8820] Reference is now made to Fig. 633, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 633(GR633) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8821] GR633 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR633 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8822] GR633 GENE encodes GR633 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8823] GR633 PRECURSOR RNA folds spatially, forming GR633 FOLDED PRECURSOR RNA . It is appreciated that GR633 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR633 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8824] GR633 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8825] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8826] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8827] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8828] It is appreciated that specific functions, and accordingly utilities, of GR633 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR633 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8829] Reference is now made to Fig. 634, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record

634(GR634) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8830] GR634 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR634 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8831] GR634 GENE encodes GR634 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8832] GR634 PRECURSOR RNA folds spatially, forming GR634 FOLDED PRECURSOR RNA . It is appreciated that GR634 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR634 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8833] GR634 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM

precursor RNAs, GAM52 PRECURSOR, GAM367 PRECURSOR and GAM395 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8834] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM52 RNA, GAM367 RNA and GAM395 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8835] GAM52 RNA binds complimentarily to a target binding site located in an untranslated region of GAM52 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 52A, thereby inhibiting translation of GAM52 TARGET RNA into GAM52 TARGET PROTEIN, both of Fig. 52A.

[8836] GAM367 RNA binds complimentarily to a target binding site located in an untranslated region of GAM367 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 367A, thereby inhibiting translation of GAM367 TARGET RNA into GAM367 TARGET PROTEIN, both of Fig. 367A.

[8837] GAM395 RNA binds complimentarily to a target binding site located in an untranslated region of GAM395 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 395A, thereby inhibiting translation of GAM395 TARGET RNA into GAM395 TARGET PROTEIN, both of Fig. 395A.

[8838] It is appreciated that specific functions, and accordingly utilities, of GR634 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR634 GENE: GAM52 TARGET PROTEIN, GAM367 TARGET PROTEIN and GAM395 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 52D, 367D and 395D

[8839] Reference is now made to Fig. 635, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 635(GR635) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8840] GR635 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR635 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8841] GR635 GENE encodes GR635 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8842] GR635 PRECURSOR RNA folds spatially, forming GR635 FOLDED PRECURSOR RNA . It is appreciated that GR635 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR635 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8843] GR635 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM216 PRECURSOR and GAM286 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8844] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM216 RNA and GAM286 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8845] GAM216 RNA binds complimentarily to a target binding site located in an untranslated region of GAM216 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 216A, thereby inhibiting translation of GAM216 TARGET RNA into GAM216 TARGET PROTEIN, both of Fig. 216A.

[8846] GAM286 RNA binds complimentarily to a target binding site located in an untranslated region of GAM286 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 286A, thereby inhibiting translation of GAM286 TARGET RNA into GAM286 TARGET PROTEIN, both of Fig. 286A.

[8847] It is appreciated that specific functions, and accordingly utilities, of GR635 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR635 GENE: GAM216 TARGET PROTEIN and GAM286

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 216D and 286D

[8848] Reference is now made to Fig. 636, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 636(GR636) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8849] GR636 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR636 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8850] GR636 GENE encodes GR636 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8851] GR636 PRECURSOR RNA folds spatially, forming GR636 FOLDED PRECURSOR RNA . It is appreciated that GR636 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR636 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8852] GR636 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8853] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8854] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8855] GAM448 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8856] It is appreciated that specific functions, and accordingly utilities, of GR636 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR636 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8857] Reference is now made to Fig. 637, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 637(GR637) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8858] GR637 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR637 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8859] GR637 GENE encodes GR637 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8860] GR637 PRECURSOR RNA folds spatially, forming GR637 FOLDED PRECURSOR RNA . It is appreciated that GR637 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR637 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8861] GR637 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM188 PRECURSOR and GAM234 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8862] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM188 RNA and GAM234 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8863] GAM188 RNA binds complimentarily to a target binding site located in an untranslated region of GAM188 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 188A, thereby inhibiting translation of GAM188 TARGET RNA into GAM188 TARGET PROTEIN, both of Fig. 188A.

[8864] GAM234 RNA binds complimentarily to a target binding site located in an untranslated region of GAM234 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 234A, thereby inhibiting translation of GAM234 TARGET RNA into GAM234 TARGET PROTEIN, both of Fig. 234A.

[8865] It is appreciated that specific functions, and accordingly utilities, of GR637 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR637 GENE: GAM188 TARGET PROTEIN and GAM234 TARGET PROTEIN. The function of these target genes is

elaborated hereinabove with reference to Figs. 188D and 234D

[8866] Reference is now made to Fig. 638, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 638(GR638) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8867] GR638 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR638 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8868] GR638 GENE encodes GR638 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8869] GR638 PRECURSOR RNA folds spatially, forming GR638 FOLDED PRECURSOR RNA . It is appreciated that GR638 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR638 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nu-

cleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8870] GR638 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8871] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8872] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8873] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[8874] It is appreciated that specific functions, and accordingly utilities, of GR638 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR638 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[8875] Reference is now made to Fig. 639, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 639(GR639) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8876] GR639 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which

GR639 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8877] GR639 GENE encodes GR639 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8878] GR639 PRECURSOR RNA folds spatially, forming GR639 FOLDED PRECURSOR RNA . It is appreciated that GR639 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR639 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8879] GR639 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM102 PRECURSOR and GAM128 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8880] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM102 RNA

and GAM128 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8881] GAM102 RNA binds complimentarily to a target binding site located in an untranslated region of GAM102 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 102A, thereby inhibiting translation of GAM102 TARGET RNA into GAM102 TARGET PROTEIN, both of Fig. 102A.

[8882] GAM128 RNA binds complimentarily to a target binding site located in an untranslated region of GAM128 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 128A, thereby inhibiting translation of GAM128 TARGET RNA into GAM128 TARGET PROTEIN, both of Fig. 128A.

[8883] It is appreciated that specific functions, and accordingly utilities, of GR639 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR639 GENE: GAM102 TARGET PROTEIN and GAM128 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 102D and

[8884] Reference is now made to Fig. 640, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 640(GR640) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8885] GR640 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR640 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8886] GR640 GENE encodes GR640 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8887] GR640 PRECURSOR RNA folds spatially, forming GR640 FOLDED PRECURSOR RNA . It is appreciated that GR640 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR640 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-re-

versed sequence of the second half thereof, as is well known in the art.

[8888] GR640 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM197 PRECURSOR and GAM475 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8889] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM197 RNA and GAM475 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8890] GAM197 RNA binds complimentarily to a target binding site located in an untranslated region of GAM197 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 197A, thereby inhibiting translation of GAM197 TARGET RNA into GAM197 TARGET PROTEIN, both of Fig. 197A.

[8891] GAM475 RNA binds complimentarily to a target binding site located in an untranslated region of GAM475 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 475A, thereby inhibiting translation of GAM475 TARGET RNA into GAM475 TARGET PROTEIN, both of Fig. 475A.

[8892] It is appreciated that specific functions, and accordingly utilities, of GR640 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR640 GENE: GAM197 TARGET PROTEIN and GAM475 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 197D and 475D

[8893] Reference is now made to Fig. 641, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 641(GR641) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8894] GR641 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR641 GENE was detected is described hereinabove with

reference to Figs. 6-15.

[8895] GR641 GENE encodes GR641 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8896] GR641 PRECURSOR RNA folds spatially, forming GR641 FOLDED PRECURSOR RNA . It is appreciated that GR641 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR641 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8897] GR641 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM515 PRECURSOR and GAM516 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8898] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM515 RNA and GAM516 RNA respectively, each of which GAM RNAs

corresponding to GAM RNA of Fig. 8.

[8899] GAM515 RNA binds complimentarily to a target binding site located in an untranslated region of GAM515 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 515A, thereby inhibiting translation of GAM515 TARGET RNA into GAM515 TARGET PROTEIN, both of Fig. 515A.

[8900] GAM516 RNA binds complimentarily to a target binding site located in an untranslated region of GAM516 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 516A, thereby inhibiting translation of GAM516 TARGET RNA into GAM516 TARGET PROTEIN, both of Fig. 516A.

[8901] It is appreciated that specific functions, and accordingly utilities, of GR641 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR641 GENE: GAM515 TARGET PROTEIN and GAM516 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 515D and 516D

[8902] Reference is now made to Fig. 642, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 642(GR642) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8903] GR642 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR642 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8904] GR642 GENE encodes GR642 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8905] GR642 PRECURSOR RNA folds spatially, forming GR642 FOLDED PRECURSOR RNA . It is appreciated that GR642 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR642 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well

known in the art.

[8906] GR642 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM81 PRECURSOR and GAM490 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8907] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM81 RNA and GAM490 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8908] GAM81 RNA binds complimentarily to a target binding site located in an untranslated region of GAM81 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 81A, thereby inhibiting translation of GAM81 TARGET RNA into GAM81 TARGET PROTEIN, both of Fig. 81A.

[8909] GAM490 RNA binds complimentarily to a target binding site located in an untranslated region of GAM490 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 490A, thereby inhibiting translation of GAM490 TARGET RNA into GAM490 TARGET PROTEIN, both of Fig. 490A.

[8910] It is appreciated that specific functions, and accordingly utilities, of GR642 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR642 GENE: GAM81 TARGET PROTEIN and GAM490 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 81D and 490D

[8911] Reference is now made to Fig. 643, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 643(GR643) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8912] GR643 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR643 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8913] GR643 GENE encodes GR643 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8914] GR643 PRECURSOR RNA folds spatially, forming GR643 FOLDED PRECURSOR RNA . It is appreciated that GR643 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR643 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8915] GR643 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM364 PRECURSOR and GAM538 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8916] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM364 RNA and GAM538 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8917] GAM364 RNA binds complimentarily to a target binding site located in an untranslated region of GAM364 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 364A, thereby inhibiting translation of GAM364 TARGET RNA into GAM364 TARGET PROTEIN, both of Fig. 364A.

[8918] GAM538 RNA binds complimentarily to a target binding site located in an untranslated region of GAM538 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 538A, thereby inhibiting translation of GAM538 TARGET RNA into GAM538 TARGET PROTEIN, both of Fig. 538A.

[8919] It is appreciated that specific functions, and accordingly utilities, of GR643 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR643 GENE: GAM364 TARGET PROTEIN and GAM538 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 364D and 538D

[8920] Reference is now made to Fig. 644, which is a simplified

diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 644(GR644) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8921] GR644 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR644 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8922] GR644 GENE encodes GR644 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8923] GR644 PRECURSOR RNA folds spatially, forming GR644 FOLDED PRECURSOR RNA . It is appreciated that GR644 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR644 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8924] GR644 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM321 PRECURSOR and GAM422 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8925] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM321 RNA and GAM422 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8926] GAM321 RNA binds complimentarily to a target binding site located in an untranslated region of GAM321 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 321A, thereby inhibiting translation of GAM321 TARGET RNA into GAM321 TARGET PROTEIN, both of Fig. 321A.

[8927] GAM422 RNA binds complimentarily to a target binding site located in an untranslated region of GAM422 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 422A, thereby inhibiting transla-

tion of GAM422 TARGET RNA into GAM422 TARGET PROTEIN, both of Fig. 422A.

[8928] It is appreciated that specific functions, and accordingly utilities, of GR644 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR644 GENE: GAM321 TARGET PROTEIN and GAM422 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 321D and 422D

[8929] Reference is now made to Fig. 645, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 645(GR645) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8930] GR645 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR645 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8931] GR645 GENE encodes GR645 PRECURSOR RNA, an RNA

molecule, typically several hundred nucleotides long.

[8932] GR645 PRECURSOR RNA folds spatially, forming GR645 FOLDED PRECURSOR RNA . It is appreciated that GR645 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR645 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8933] GR645 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM147 PRECURSOR and GAM361 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8934] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM147 RNA and GAM361 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8935] GAM147 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM147 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 147A, thereby inhibiting translation of GAM147 TARGET RNA into GAM147 TARGET PROTEIN, both of Fig. 147A.

[8936] GAM361 RNA binds complimentarily to a target binding site located in an untranslated region of GAM361 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 361A, thereby inhibiting translation of GAM361 TARGET RNA into GAM361 TARGET PROTEIN, both of Fig. 361A.

[8937] It is appreciated that specific functions, and accordingly utilities, of GR645 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR645 GENE: GAM147 TARGET PROTEIN and GAM361 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 147D and 361D

[8938] Reference is now made to Fig. 646, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 646(GR646) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8939] GR646 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR646 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8940] GR646 GENE encodes GR646 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8941] GR646 PRECURSOR RNA folds spatially, forming GR646 FOLDED PRECURSOR RNA . It is appreciated that GR646 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR646 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8942] GR646 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM230 PRECURSOR and GAM307 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8943] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM230 RNA and GAM307 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8944] GAM230 RNA binds complimentarily to a target binding site located in an untranslated region of GAM230 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 230A, thereby inhibiting translation of GAM230 TARGET RNA into GAM230 TARGET PROTEIN, both of Fig. 230A.

[8945] GAM307 RNA binds complimentarily to a target binding site located in an untranslated region of GAM307 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 307A, thereby inhibiting translation of GAM307 TARGET RNA into GAM307 TARGET PRO-

TEIN, both of Fig. 307A.

[8946] It is appreciated that specific functions, and accordingly utilities, of GR646 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR646 GENE: GAM230 TARGET PROTEIN and GAM307 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 230D and 307D

[8947] Reference is now made to Fig. 647, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 647(GR647) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8948] GR647 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR647 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8949] GR647 GENE encodes GR647 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8950] GR647 PRECURSOR RNA folds spatially, forming GR647 FOLDED PRECURSOR RNA . It is appreciated that GR647 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR647 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8951] GR647 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM60 PRECURSOR and GAM414 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8952] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM60 RNA and GAM414 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8953] GAM60 RNA binds complimentarily to a target binding site located in an untranslated region of GAM60 TARGET RNA,

which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 60A, thereby inhibiting translation of GAM60 TARGET RNA into GAM60 TARGET PROTEIN, both of Fig. 60A.

[8954] GAM414 RNA binds complimentarily to a target binding site located in an untranslated region of GAM414 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 414A, thereby inhibiting translation of GAM414 TARGET RNA into GAM414 TARGET PROTEIN, both of Fig. 414A.

[8955] It is appreciated that specific functions, and accordingly utilities, of GR647 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR647 GENE: GAM60 TARGET PROTEIN and GAM414 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 60D and 414D

[8956] Reference is now made to Fig. 648, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record

648(GR648) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8957] GR648 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR648 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8958] GR648 GENE encodes GR648 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8959] GR648 PRECURSOR RNA folds spatially, forming GR648 FOLDED PRECURSOR RNA . It is appreciated that GR648 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR648 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8960] GR648 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM

precursor RNAs, GAM218 PRECURSOR and GAM447 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8961] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM447 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8962] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[8963] GAM447 RNA binds complimentarily to a target binding site located in an untranslated region of GAM447 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 447A, thereby inhibiting translation of GAM447 TARGET RNA into GAM447 TARGET PROTEIN, both of Fig. 447A.

[8964] It is appreciated that specific functions, and accordingly utilities, of GR648 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR648 GENE: GAM218 TARGET PROTEIN and GAM447 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 447D

[8965] Reference is now made to Fig. 649, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 649(GR649) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8966] GR649 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR649 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8967] GR649 GENE encodes GR649 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8968] GR649 PRECURSOR RNA folds spatially, forming GR649

FOLDED PRECURSOR RNA . It is appreciated that GR649 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR649 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8969] GR649 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM88 PRECURSOR and GAM363 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8970] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM88 RNA and GAM363 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8971] GAM88 RNA binds complimentarily to a target binding site located in an untranslated region of GAM88 TARGET RNA, which target binding site corresponds to a target binding

site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 88A, thereby inhibiting translation of GAM88 TARGET RNA into GAM88 TARGET PROTEIN, both of Fig. 88A.

[8972] GAM363 RNA binds complimentarily to a target binding site located in an untranslated region of GAM363 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 363A, thereby inhibiting translation of GAM363 TARGET RNA into GAM363 TARGET PROTEIN, both of Fig. 363A.

[8973] It is appreciated that specific functions, and accordingly utilities, of GR649 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR649 GENE: GAM88 TARGET PROTEIN and GAM363 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 88D and 363D

[8974] Reference is now made to Fig. 650, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 650(GR650) gene, which encodes an operon-like cluster

of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8975] GR650 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR650 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8976] GR650 GENE encodes GR650 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8977] GR650 PRECURSOR RNA folds spatially, forming GR650 FOLDED PRECURSOR RNA . It is appreciated that GR650 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR650 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8978] GR650 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM99 PRECURSOR, GAM434 PRECUR-

SOR and GAM492 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8979] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM99 RNA, GAM434 RNA and GAM492 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8980] GAM99 RNA binds complimentarily to a target binding site located in an untranslated region of GAM99 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 99A, thereby inhibiting translation of GAM99 TARGET RNA into GAM99 TARGET PROTEIN, both of Fig. 99A.

[8981] GAM434 RNA binds complimentarily to a target binding site located in an untranslated region of GAM434 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 434A, thereby inhibiting translation of GAM434 TARGET RNA into GAM434 TARGET PROTEIN, both of Fig. 434A.

[8982] GAM492 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM492 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 492A, thereby inhibiting translation of GAM492 TARGET RNA into GAM492 TARGET PROTEIN, both of Fig. 492A.

[8983] It is appreciated that specific functions, and accordingly utilities, of GR650 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR650 GENE: GAM99 TARGET PROTEIN, GAM434 TARGET PROTEIN and GAM492 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 99D, 434D and 492D

[8984] Reference is now made to Fig. 651, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 651(GR651) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8985] GR651 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR651 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8986] GR651 GENE encodes GR651 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8987] GR651 PRECURSOR RNA folds spatially, forming GR651 FOLDED PRECURSOR RNA . It is appreciated that GR651 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR651 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8988] GR651 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM83 PRECURSOR and GAM132 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8989] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM83 RNA and GAM132 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8990] GAM83 RNA binds complimentarily to a target binding site located in an untranslated region of GAM83 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 83A, thereby inhibiting translation of GAM83 TARGET RNA into GAM83 TARGET PROTEIN, both of Fig. 83A.

[8991] GAM132 RNA binds complimentarily to a target binding site located in an untranslated region of GAM132 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 132A, thereby inhibiting translation of GAM132 TARGET RNA into GAM132 TARGET PROTEIN, both of Fig. 132A.

[8992] It is appreciated that specific functions, and accordingly utilities, of GR651 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR651 GENE: GAM83 TARGET PROTEIN and GAM132 TARGET PROTEIN. The function of these target genes is

elaborated hereinabove with reference to Figs. 83D and 132D

[8993] Reference is now made to Fig. 652, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 652(GR652) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[8994] GR652 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR652 GENE was detected is described hereinabove with reference to Figs. 6-15.

[8995] GR652 GENE encodes GR652 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[8996] GR652 PRECURSOR RNA folds spatially, forming GR652 FOLDED PRECURSOR RNA . It is appreciated that GR652 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR652 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nu-

cleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[8997] GR652 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM50 PRECURSOR and GAM300 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[8998] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM50 RNA and GAM300 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[8999] GAM50 RNA binds complimentarily to a target binding site located in an untranslated region of GAM50 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 50A, thereby inhibiting translation of GAM50 TARGET RNA into GAM50 TARGET PROTEIN, both of Fig. 50A.

[9000] GAM300 RNA binds complimentarily to a target binding site located in an untranslated region of GAM300 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 300A, thereby inhibiting translation of GAM300 TARGET RNA into GAM300 TARGET PROTEIN, both of Fig. 300A.

[9001] It is appreciated that specific functions, and accordingly utilities, of GR652 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR652 GENE: GAM50 TARGET PROTEIN and GAM300 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 50D and 300D

[9002] Reference is now made to Fig. 653, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 653(GR653) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9003] GR653 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which

GR653 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9004] GR653 GENE encodes GR653 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9005] GR653 PRECURSOR RNA folds spatially, forming GR653 FOLDED PRECURSOR RNA . It is appreciated that GR653 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR653 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9006] GR653 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM64 PRECURSOR and GAM169 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9007] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM64 RNA

and GAM169 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9008] GAM64 RNA binds complimentarily to a target binding site located in an untranslated region of GAM64 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 64A, thereby inhibiting translation of GAM64 TARGET RNA into GAM64 TARGET PROTEIN, both of Fig. 64A.

[9009] GAM169 RNA binds complimentarily to a target binding site located in an untranslated region of GAM169 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 169A, thereby inhibiting translation of GAM169 TARGET RNA into GAM169 TARGET PROTEIN, both of Fig. 169A.

[9010] It is appreciated that specific functions, and accordingly utilities, of GR653 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR653 GENE: GAM64 TARGET PROTEIN and GAM169 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 64D and

[9011] Reference is now made to Fig. 654, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 654(GR654) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9012] GR654 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR654 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9013] GR654 GENE encodes GR654 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9014] GR654 PRECURSOR RNA folds spatially, forming GR654 FOLDED PRECURSOR RNA . It is appreciated that GR654 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR654 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-re-

versed sequence of the second half thereof, as is well known in the art.

[9015] GR654 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM133 PRECURSOR and GAM284 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9016] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM133 RNA and GAM284 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9017] GAM133 RNA binds complimentarily to a target binding site located in an untranslated region of GAM133 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 133A, thereby inhibiting translation of GAM133 TARGET RNA into GAM133 TARGET PROTEIN, both of Fig. 133A.

[9018] GAM284 RNA binds complimentarily to a target binding site located in an untranslated region of GAM284 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 284A, thereby inhibiting translation of GAM284 TARGET RNA into GAM284 TARGET PROTEIN, both of Fig. 284A.

[9019] It is appreciated that specific functions, and accordingly utilities, of GR654 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR654 GENE: GAM133 TARGET PROTEIN and GAM284 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 133D and 284D

[9020] Reference is now made to Fig. 655, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 655(GR655) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9021] GR655 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR655 GENE was detected is described hereinabove with

reference to Figs. 6-15.

[9022] GR655 GENE encodes GR655 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9023] GR655 PRECURSOR RNA folds spatially, forming GR655 FOLDED PRECURSOR RNA . It is appreciated that GR655 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR655 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9024] GR655 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM447 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9025] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM447 RNA respectively, each of which GAM RNAs

corresponding to GAM RNA of Fig. 8.

[9026] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[9027] GAM447 RNA binds complimentarily to a target binding site located in an untranslated region of GAM447 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 447A, thereby inhibiting translation of GAM447 TARGET RNA into GAM447 TARGET PROTEIN, both of Fig. 447A.

[9028] It is appreciated that specific functions, and accordingly utilities, of GR655 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR655 GENE: GAM218 TARGET PROTEIN and GAM447 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 447D

[9029] Reference is now made to Fig. 656, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 656(GR656) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9030] GR656 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR656 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9031] GR656 GENE encodes GR656 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9032] GR656 PRECURSOR RNA folds spatially, forming GR656 FOLDED PRECURSOR RNA . It is appreciated that GR656 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR656 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well

known in the art.

[9033] GR656 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM47 PRECURSOR and GAM430 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9034] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM47 RNA and GAM430 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9035] GAM47 RNA binds complimentarily to a target binding site located in an untranslated region of GAM47 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 47A, thereby inhibiting translation of GAM47 TARGET RNA into GAM47 TARGET PROTEIN, both of Fig. 47A.

[9036] GAM430 RNA binds complimentarily to a target binding site located in an untranslated region of GAM430 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 430A, thereby inhibiting translation of GAM430 TARGET RNA into GAM430 TARGET PROTEIN, both of Fig. 430A.

[9037] It is appreciated that specific functions, and accordingly utilities, of GR656 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR656 GENE: GAM47 TARGET PROTEIN and GAM430 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 47D and 430D

[9038] Reference is now made to Fig. 657, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 657(GR657) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9039] GR657 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR657 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9040] GR657 GENE encodes GR657 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9041] GR657 PRECURSOR RNA folds spatially, forming GR657 FOLDED PRECURSOR RNA . It is appreciated that GR657 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR657 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9042] GR657 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM282 PRECURSOR and GAM290 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9043] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM282 RNA and GAM290 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9044] GAM282 RNA binds complimentarily to a target binding site located in an untranslated region of GAM282 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 282A, thereby inhibiting translation of GAM282 TARGET RNA into GAM282 TARGET PROTEIN, both of Fig. 282A.

[9045] GAM290 RNA binds complimentarily to a target binding site located in an untranslated region of GAM290 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 290A, thereby inhibiting translation of GAM290 TARGET RNA into GAM290 TARGET PROTEIN, both of Fig. 290A.

[9046] It is appreciated that specific functions, and accordingly utilities, of GR657 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR657 GENE: GAM282 TARGET PROTEIN and GAM290 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 282D and 290D

[9047] Reference is now made to Fig. 658, which is a simplified

diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 658(GR658) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9048] GR658 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR658 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9049] GR658 GENE encodes GR658 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9050] GR658 PRECURSOR RNA folds spatially, forming GR658 FOLDED PRECURSOR RNA . It is appreciated that GR658 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR658 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9051] GR658 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM80 PRECURSOR, GAM424 PRECURSOR and GAM505 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9052] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM80 RNA, GAM424 RNA and GAM505 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9053] GAM80 RNA binds complimentarily to a target binding site located in an untranslated region of GAM80 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 80A, thereby inhibiting translation of GAM80 TARGET RNA into GAM80 TARGET PROTEIN, both of Fig. 80A.

[9054] GAM424 RNA binds complimentarily to a target binding site located in an untranslated region of GAM424 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 424A, thereby inhibiting transla-

tion of GAM424 TARGET RNA into GAM424 TARGET PROTEIN, both of Fig. 424A.

[9055] GAM505 RNA binds complimentarily to a target binding site located in an untranslated region of GAM505 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 505A, thereby inhibiting translation of GAM505 TARGET RNA into GAM505 TARGET PROTEIN, both of Fig. 505A.

[9056] It is appreciated that specific functions, and accordingly utilities, of GR658 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR658 GENE: GAM80 TARGET PROTEIN, GAM424 TARGET PROTEIN and GAM505 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 80D, 424D and 505D

[9057] Reference is now made to Fig. 659, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 659(GR659) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the

function and utility of which at least one target gene is known in the art.

[9058] GR659 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR659 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9059] GR659 GENE encodes GR659 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9060] GR659 PRECURSOR RNA folds spatially, forming GR659 FOLDED PRECURSOR RNA . It is appreciated that GR659 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR659 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9061] GR659 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM218 PRECURSOR and GAM448 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECUR-

SOR RNA of Fig. 8.

[9062] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM218 RNA and GAM448 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9063] GAM218 RNA binds complimentarily to a target binding site located in an untranslated region of GAM218 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 218A, thereby inhibiting translation of GAM218 TARGET RNA into GAM218 TARGET PROTEIN, both of Fig. 218A.

[9064] GAM448 RNA binds complimentarily to a target binding site located in an untranslated region of GAM448 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 448A, thereby inhibiting translation of GAM448 TARGET RNA into GAM448 TARGET PROTEIN, both of Fig. 448A.

[9065] It is appreciated that specific functions, and accordingly utilities, of GR659 GENE correlate with, and may be deduced from, the identity of the target genes, which are in-

hibited by GAM RNAs comprised in the operon-like cluster of GR659 GENE: GAM218 TARGET PROTEIN and GAM448 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 218D and 448D

[9066] Reference is now made to Fig. 660, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 660(GR660) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9067] GR660 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR660 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9068] GR660 GENE encodes GR660 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9069] GR660 PRECURSOR RNA folds spatially, forming GR660 FOLDED PRECURSOR RNA . It is appreciated that GR660 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin

structures are due to the fact that the nucleotide sequence of GR660 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9070] GR660 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM420 PRECURSOR and GAM550 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9071] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM420 RNA and GAM550 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9072] GAM420 RNA binds complimentarily to a target binding site located in an untranslated region of GAM420 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 420A, thereby inhibiting translation of GAM420 TARGET RNA into GAM420 TARGET PRO-

TEIN, both of Fig. 420A.

[9073] GAM550 RNA binds complimentarily to a target binding site located in an untranslated region of GAM550 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 550A, thereby inhibiting translation of GAM550 TARGET RNA into GAM550 TARGET PROTEIN, both of Fig. 550A.

[9074] It is appreciated that specific functions, and accordingly utilities, of GR660 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR660 GENE: GAM420 TARGET PROTEIN and GAM550 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 420D and 550D

[9075] Reference is now made to Fig. 661, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 661(GR661) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is

known in the art.

[9076] GR661 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR661 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9077] GR661 GENE encodes GR661 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9078] GR661 PRECURSOR RNA folds spatially, forming GR661 FOLDED PRECURSOR RNA . It is appreciated that GR661 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR661 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9079] GR661 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM317 PRECURSOR and GAM501 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9080] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM317 RNA and GAM501 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9081] GAM317 RNA binds complimentarily to a target binding site located in an untranslated region of GAM317 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 317A, thereby inhibiting translation of GAM317 TARGET RNA into GAM317 TARGET PROTEIN, both of Fig. 317A.

[9082] GAM501 RNA binds complimentarily to a target binding site located in an untranslated region of GAM501 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 501A, thereby inhibiting translation of GAM501 TARGET RNA into GAM501 TARGET PROTEIN, both of Fig. 501A.

[9083] It is appreciated that specific functions, and accordingly utilities, of GR661 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR661 GENE: GAM317 TARGET PROTEIN and GAM501 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 317D and 501D

[9084] Reference is now made to Fig. 662, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 662(GR662) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9085] GR662 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR662 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9086] GR662 GENE encodes GR662 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9087] GR662 PRECURSOR RNA folds spatially, forming GR662 FOLDED PRECURSOR RNA . It is appreciated that GR662 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR662 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9088] GR662 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM111 PRECURSOR and GAM242 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9089] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM111 RNA and GAM242 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9090] GAM111 RNA binds complimentarily to a target binding site located in an untranslated region of GAM111 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 111A, thereby inhibiting translation of GAM111 TARGET RNA into GAM111 TARGET PROTEIN, both of Fig. 111A.

[9091] GAM242 RNA binds complimentarily to a target binding site located in an untranslated region of GAM242 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 242A, thereby inhibiting translation of GAM242 TARGET RNA into GAM242 TARGET PROTEIN, both of Fig. 242A.

[9092] It is appreciated that specific functions, and accordingly utilities, of GR662 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR662 GENE: GAM111 TARGET PROTEIN and GAM242 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 111D and 242D

[9093] Reference is now made to Fig. 663, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 663(GR663) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9094] GR663 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR663 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9095] GR663 GENE encodes GR663 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9096] GR663 PRECURSOR RNA folds spatially, forming GR663 FOLDED PRECURSOR RNA . It is appreciated that GR663 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR663 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9097] GR663 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM135 PRECURSOR and GAM309 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9098] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM135 RNA and GAM309 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9099] GAM135 RNA binds complimentarily to a target binding site located in an untranslated region of GAM135 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 135A, thereby inhibiting translation of GAM135 TARGET RNA into GAM135 TARGET PROTEIN, both of Fig. 135A.

[9100] GAM309 RNA binds complimentarily to a target binding site located in an untranslated region of GAM309 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 309A, thereby inhibiting translation of GAM309 TARGET RNA into GAM309 TARGET PROTEIN, both of Fig. 309A.

[9101] It is appreciated that specific functions, and accordingly utilities, of GR663 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR663 GENE: GAM135 TARGET PROTEIN and GAM309

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 135D and 309D

[9102] Reference is now made to Fig. 664, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 664(GR664) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9103] GR664 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR664 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9104] GR664 GENE encodes GR664 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9105] GR664 PRECURSOR RNA folds spatially, forming GR664 FOLDED PRECURSOR RNA . It is appreciated that GR664 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR664 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9106] GR664 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM119 PRECURSOR, GAM248 PRECURSOR and GAM257 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9107] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM119 RNA, GAM248 RNA and GAM257 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9108] GAM119 RNA binds complimentarily to a target binding site located in an untranslated region of GAM119 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 119A, thereby inhibiting translation of GAM119 TARGET RNA into GAM119 TARGET PROTEIN, both of Fig. 119A.

[9109] GAM248 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM248 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 248A, thereby inhibiting translation of GAM248 TARGET RNA into GAM248 TARGET PROTEIN, both of Fig. 248A.

[9110] GAM257 RNA binds complimentarily to a target binding site located in an untranslated region of GAM257 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 257A, thereby inhibiting translation of GAM257 TARGET RNA into GAM257 TARGET PROTEIN, both of Fig. 257A.

[9111] It is appreciated that specific functions, and accordingly utilities, of GR664 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR664 GENE: GAM119 TARGET PROTEIN, GAM248 TARGET PROTEIN and GAM257 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 119D, 248D and 257D

[9112] Reference is now made to Fig. 665, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 665(GR665) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9113] GR665 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR665 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9114] GR665 GENE encodes GR665 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9115] GR665 PRECURSOR RNA folds spatially, forming GR665 FOLDED PRECURSOR RNA . It is appreciated that GR665 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR665 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9116] GR665 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM115 PRECURSOR and GAM452 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9117] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM115 RNA and GAM452 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9118] GAM115 RNA binds complimentarily to a target binding site located in an untranslated region of GAM115 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 115A, thereby inhibiting translation of GAM115 TARGET RNA into GAM115 TARGET PROTEIN, both of Fig. 115A.

[9119] GAM452 RNA binds complimentarily to a target binding site located in an untranslated region of GAM452 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 452A, thereby inhibiting translation of GAM452 TARGET RNA into GAM452 TARGET PRO-

TEIN, both of Fig. 452A.

[9120] It is appreciated that specific functions, and accordingly utilities, of GR665 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR665 GENE: GAM115 TARGET PROTEIN and GAM452 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 115D and 452D

[9121] Reference is now made to Fig. 666, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 666(GR666) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9122] GR666 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR666 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9123] GR666 GENE encodes GR666 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9124] GR666 PRECURSOR RNA folds spatially, forming GR666 FOLDED PRECURSOR RNA . It is appreciated that GR666 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR666 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9125] GR666 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM156 PRECURSOR and GAM346 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9126] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM156 RNA and GAM346 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9127] GAM156 RNA binds complimentarily to a target binding site located in an untranslated region of GAM156 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 156A, thereby inhibiting translation of GAM156 TARGET RNA into GAM156 TARGET PROTEIN, both of Fig. 156A.

[9128] GAM346 RNA binds complimentarily to a target binding site located in an untranslated region of GAM346 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 346A, thereby inhibiting translation of GAM346 TARGET RNA into GAM346 TARGET PROTEIN, both of Fig. 346A.

[9129] It is appreciated that specific functions, and accordingly utilities, of GR666 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR666 GENE: GAM156 TARGET PROTEIN and GAM346 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 156D and 346D

[9130] Reference is now made to Fig. 667, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record

667(GR667) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9131] GR667 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR667 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9132] GR667 GENE encodes GR667 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9133] GR667 PRECURSOR RNA folds spatially, forming GR667 FOLDED PRECURSOR RNA . It is appreciated that GR667 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR667 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9134] GR667 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM

precursor RNAs, GAM288 PRECURSOR and GAM405 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9135] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM288 RNA and GAM405 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9136] GAM288 RNA binds complimentarily to a target binding site located in an untranslated region of GAM288 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 288A, thereby inhibiting translation of GAM288 TARGET RNA into GAM288 TARGET PROTEIN, both of Fig. 288A.

[9137] GAM405 RNA binds complimentarily to a target binding site located in an untranslated region of GAM405 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 405A, thereby inhibiting translation of GAM405 TARGET RNA into GAM405 TARGET PROTEIN, both of Fig. 405A.

[9138] It is appreciated that specific functions, and accordingly utilities, of GR667 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR667 GENE: GAM288 TARGET PROTEIN and GAM405 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 288D and 405D

[9139] Reference is now made to Fig. 668, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 668(GR668) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9140] GR668 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR668 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9141] GR668 GENE encodes GR668 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9142] GR668 PRECURSOR RNA folds spatially, forming GR668

FOLDED PRECURSOR RNA . It is appreciated that GR668 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR668 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9143] GR668 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM259 PRECURSOR and GAM379 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9144] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM259 RNA and GAM379 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9145] GAM259 RNA binds complimentarily to a target binding site located in an untranslated region of GAM259 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 259A, thereby inhibiting translation of GAM259 TARGET RNA into GAM259 TARGET PROTEIN, both of Fig. 259A.

[9146] GAM379 RNA binds complimentarily to a target binding site located in an untranslated region of GAM379 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 379A, thereby inhibiting translation of GAM379 TARGET RNA into GAM379 TARGET PROTEIN, both of Fig. 379A.

[9147] It is appreciated that specific functions, and accordingly utilities, of GR668 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR668 GENE: GAM259 TARGET PROTEIN and GAM379 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 259D and 379D

[9148] Reference is now made to Fig. 669, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 669(GR669) gene, which encodes an operon-like cluster

of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9149] GR669 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR669 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9150] GR669 GENE encodes GR669 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9151] GR669 PRECURSOR RNA folds spatially, forming GR669 FOLDED PRECURSOR RNA . It is appreciated that GR669 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR669 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9152] GR669 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM68 PRECURSOR and GAM365 PRE-

CURSOR, each of which GAM precursor RNAs being a hair-pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9153] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM68 RNA and GAM365 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9154] GAM68 RNA binds complimentarily to a target binding site located in an untranslated region of GAM68 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 68A, thereby inhibiting translation of GAM68 TARGET RNA into GAM68 TARGET PROTEIN, both of Fig. 68A.

[9155] GAM365 RNA binds complimentarily to a target binding site located in an untranslated region of GAM365 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 365A, thereby inhibiting translation of GAM365 TARGET RNA into GAM365 TARGET PROTEIN, both of Fig. 365A.

[9156] It is appreciated that specific functions, and accordingly

utilities, of GR669 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR669 GENE: GAM68 TARGET PROTEIN and GAM365 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 68D and 365D

[9157] Reference is now made to Fig. 670, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 670(GR670) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9158] GR670 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR670 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9159] GR670 GENE encodes GR670 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9160] GR670 PRECURSOR RNA folds spatially, forming GR670 FOLDED PRECURSOR RNA . It is appreciated that GR670

FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR670 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9161] GR670 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM97 PRECURSOR and GAM316 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9162] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM97 RNA and GAM316 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9163] GAM97 RNA binds complimentarily to a target binding site located in an untranslated region of GAM97 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING

SITE III of Fig. 97A, thereby inhibiting translation of GAM97 TARGET RNA into GAM97 TARGET PROTEIN, both of Fig. 97A.

[9164] GAM316 RNA binds complimentarily to a target binding site located in an untranslated region of GAM316 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 316A, thereby inhibiting translation of GAM316 TARGET RNA into GAM316 TARGET PROTEIN, both of Fig. 316A.

[9165] It is appreciated that specific functions, and accordingly utilities, of GR670 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR670 GENE: GAM97 TARGET PROTEIN and GAM316 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 97D and 316D

[9166] Reference is now made to Fig. 671, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 671(GR671) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn

modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9167] GR671 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR671 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9168] GR671 GENE encodes GR671 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9169] GR671 PRECURSOR RNA folds spatially, forming GR671 FOLDED PRECURSOR RNA . It is appreciated that GR671 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR671 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9170] GR671 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM214 PRECURSOR and GAM450 PRECURSOR, each of which GAM precursor RNAs being a hair-

pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9171] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM214 RNA and GAM450 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9172] GAM214 RNA binds complimentarily to a target binding site located in an untranslated region of GAM214 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 214A, thereby inhibiting translation of GAM214 TARGET RNA into GAM214 TARGET PROTEIN, both of Fig. 214A.

[9173] GAM450 RNA binds complimentarily to a target binding site located in an untranslated region of GAM450 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 450A, thereby inhibiting translation of GAM450 TARGET RNA into GAM450 TARGET PROTEIN, both of Fig. 450A.

[9174] It is appreciated that specific functions, and accordingly utilities, of GR671 GENE correlate with, and may be de-

duced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR671 GENE: GAM214 TARGET PROTEIN and GAM450 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 214D and 450D

[9175] Reference is now made to Fig. 672, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 672(GR672) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9176] GR672 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR672 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9177] GR672 GENE encodes GR672 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9178] GR672 PRECURSOR RNA folds spatially, forming GR672 FOLDED PRECURSOR RNA . It is appreciated that GR672 FOLDED PRECURSOR RNA comprises a plurality of what is

known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR672 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9179] GR672 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM334 PRECURSOR and GAM390 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9180] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM334 RNA and GAM390 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9181] GAM334 RNA binds complimentarily to a target binding site located in an untranslated region of GAM334 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 334A, thereby inhibiting transla-

tion of GAM334 TARGET RNA into GAM334 TARGET PROTEIN, both of Fig. 334A.

[9182] GAM390 RNA binds complimentarily to a target binding site located in an untranslated region of GAM390 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 390A, thereby inhibiting translation of GAM390 TARGET RNA into GAM390 TARGET PROTEIN, both of Fig. 390A.

[9183] It is appreciated that specific functions, and accordingly utilities, of GR672 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR672 GENE: GAM334 TARGET PROTEIN and GAM390 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 334D and 390D

[9184] Reference is now made to Fig. 673, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 673(GR673) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the

function and utility of which at least one target gene is known in the art.

[9185] GR673 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR673 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9186] GR673 GENE encodes GR673 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9187] GR673 PRECURSOR RNA folds spatially, forming GR673 FOLDED PRECURSOR RNA . It is appreciated that GR673 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR673 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9188] GR673 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM275 PRECURSOR and GAM415 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9189] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM275 RNA and GAM415 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9190] GAM275 RNA binds complimentarily to a target binding site located in an untranslated region of GAM275 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 275A, thereby inhibiting translation of GAM275 TARGET RNA into GAM275 TARGET PROTEIN, both of Fig. 275A.

[9191] GAM415 RNA binds complimentarily to a target binding site located in an untranslated region of GAM415 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 415A, thereby inhibiting translation of GAM415 TARGET RNA into GAM415 TARGET PROTEIN, both of Fig. 415A.

[9192] It is appreciated that specific functions, and accordingly utilities, of GR673 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR673 GENE: GAM275 TARGET PROTEIN and GAM415 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 275D and 415D

[9193] Reference is now made to Fig. 674, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record

674(GR674) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9194] GR674 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR674 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9195] GR674 GENE encodes GR674 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9196] GR674 PRECURSOR RNA folds spatially, forming GR674 FOLDED PRECURSOR RNA . It is appreciated that GR674 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR674 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9197] GR674 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM

precursor RNAs, GAM44 PRECURSOR, GAM403 PRECURSOR and GAM520 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9198] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM44 RNA, GAM403 RNA and GAM520 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9199] GAM44 RNA binds complimentarily to a target binding site located in an untranslated region of GAM44 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 44A, thereby inhibiting translation of GAM44 TARGET RNA into GAM44 TARGET PROTEIN, both of Fig. 44A.

[9200] GAM403 RNA binds complimentarily to a target binding site located in an untranslated region of GAM403 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 403A, thereby inhibiting translation of GAM403 TARGET RNA into GAM403 TARGET PROTEIN, both of Fig. 403A.

[9201] GAM520 RNA binds complimentarily to a target binding site located in an untranslated region of GAM520 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 520A, thereby inhibiting translation of GAM520 TARGET RNA into GAM520 TARGET PROTEIN, both of Fig. 520A.

[9202] It is appreciated that specific functions, and accordingly utilities, of GR674 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR674 GENE: GAM44 TARGET PROTEIN, GAM403 TARGET PROTEIN and GAM520 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 44D, 403D and 520D

[9203] Reference is now made to Fig. 675, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 675(GR675) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9204] GR675 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR675 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9205] GR675 GENE encodes GR675 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9206] GR675 PRECURSOR RNA folds spatially, forming GR675 FOLDED PRECURSOR RNA . It is appreciated that GR675 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR675 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9207] GR675 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM95 PRECURSOR and GAM261 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9208] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM95 RNA and GAM261 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9209] GAM95 RNA binds complimentarily to a target binding site located in an untranslated region of GAM95 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 95A, thereby inhibiting translation of GAM95 TARGET RNA into GAM95 TARGET PROTEIN, both of Fig. 95A.

[9210] GAM261 RNA binds complimentarily to a target binding site located in an untranslated region of GAM261 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 261A, thereby inhibiting translation of GAM261 TARGET RNA into GAM261 TARGET PROTEIN, both of Fig. 261A.

[9211] It is appreciated that specific functions, and accordingly utilities, of GR675 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR675 GENE: GAM95 TARGET PROTEIN and GAM261

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 95D and 261D

[9212] Reference is now made to Fig. 676, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 676(GR676) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9213] GR676 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR676 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9214] GR676 GENE encodes GR676 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9215] GR676 PRECURSOR RNA folds spatially, forming GR676 FOLDED PRECURSOR RNA . It is appreciated that GR676 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR676 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9216] GR676 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM229 PRECURSOR and GAM370 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9217] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM229 RNA and GAM370 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9218] GAM229 RNA binds complimentarily to a target binding site located in an untranslated region of GAM229 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 229A, thereby inhibiting translation of GAM229 TARGET RNA into GAM229 TARGET PROTEIN, both of Fig. 229A.

[9219] GAM370 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM370 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 370A, thereby inhibiting translation of GAM370 TARGET RNA into GAM370 TARGET PROTEIN, both of Fig. 370A.

[9220] It is appreciated that specific functions, and accordingly utilities, of GR676 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR676 GENE: GAM229 TARGET PROTEIN and GAM370 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 229D and 370D

[9221] Reference is now made to Fig. 677, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 677(GR677) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9222] GR677 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR677 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9223] GR677 GENE encodes GR677 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9224] GR677 PRECURSOR RNA folds spatially, forming GR677 FOLDED PRECURSOR RNA . It is appreciated that GR677 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR677 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9225] GR677 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM158 PRECURSOR and GAM466 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9226] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM158 RNA and GAM466 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9227] GAM158 RNA binds complimentarily to a target binding site located in an untranslated region of GAM158 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 158A, thereby inhibiting translation of GAM158 TARGET RNA into GAM158 TARGET PROTEIN, both of Fig. 158A.

[9228] GAM466 RNA binds complimentarily to a target binding site located in an untranslated region of GAM466 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 466A, thereby inhibiting translation of GAM466 TARGET RNA into GAM466 TARGET PROTEIN, both of Fig. 466A.

[9229] It is appreciated that specific functions, and accordingly utilities, of GR677 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR677 GENE: GAM158 TARGET PROTEIN and GAM466 TARGET PROTEIN. The function of these target genes is

elaborated hereinabove with reference to Figs. 158D and 466D

[9230] Reference is now made to Fig. 678, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 678(GR678) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9231] GR678 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR678 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9232] GR678 GENE encodes GR678 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9233] GR678 PRECURSOR RNA folds spatially, forming GR678 FOLDED PRECURSOR RNA . It is appreciated that GR678 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR678 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nu-

cleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9234] GR678 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM350 PRECURSOR and GAM470 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9235] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM350 RNA and GAM470 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9236] GAM350 RNA binds complimentarily to a target binding site located in an untranslated region of GAM350 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 350A, thereby inhibiting translation of GAM350 TARGET RNA into GAM350 TARGET PROTEIN, both of Fig. 350A.

[9237] GAM470 RNA binds complimentarily to a target binding site located in an untranslated region of GAM470 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 470A, thereby inhibiting translation of GAM470 TARGET RNA into GAM470 TARGET PROTEIN, both of Fig. 470A.

[9238] It is appreciated that specific functions, and accordingly utilities, of GR678 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR678 GENE: GAM350 TARGET PROTEIN and GAM470 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 350D and 470D

[9239] Reference is now made to Fig. 679, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 679(GR679) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9240] GR679 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which

GR679 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9241] GR679 GENE encodes GR679 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9242] GR679 PRECURSOR RNA folds spatially, forming GR679 FOLDED PRECURSOR RNA . It is appreciated that GR679 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR679 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9243] GR679 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM143 PRECURSOR and GAM398 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9244] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM143 RNA

and GAM398 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9245] GAM143 RNA binds complimentarily to a target binding site located in an untranslated region of GAM143 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 143A, thereby inhibiting translation of GAM143 TARGET RNA into GAM143 TARGET PROTEIN, both of Fig. 143A.

[9246] GAM398 RNA binds complimentarily to a target binding site located in an untranslated region of GAM398 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 398A, thereby inhibiting translation of GAM398 TARGET RNA into GAM398 TARGET PROTEIN, both of Fig. 398A.

[9247] It is appreciated that specific functions, and accordingly utilities, of GR679 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR679 GENE: GAM143 TARGET PROTEIN and GAM398 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 143D and

[9248] Reference is now made to Fig. 680, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 680(GR680) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9249] GR680 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR680 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9250] GR680 GENE encodes GR680 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9251] GR680 PRECURSOR RNA folds spatially, forming GR680 FOLDED PRECURSOR RNA . It is appreciated that GR680 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR680 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-re-

versed sequence of the second half thereof, as is well known in the art.

[9252] GR680 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM526 PRECURSOR and GAM541 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9253] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM526 RNA and GAM541 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9254] GAM526 RNA binds complimentarily to a target binding site located in an untranslated region of GAM526 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 526A, thereby inhibiting translation of GAM526 TARGET RNA into GAM526 TARGET PROTEIN, both of Fig. 526A.

[9255] GAM541 RNA binds complimentarily to a target binding site located in an untranslated region of GAM541 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 541A, thereby inhibiting translation of GAM541 TARGET RNA into GAM541 TARGET PROTEIN, both of Fig. 541A.

[9256] It is appreciated that specific functions, and accordingly utilities, of GR680 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR680 GENE: GAM526 TARGET PROTEIN and GAM541 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 526D and 541D

[9257] Reference is now made to Fig. 681, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 681(GR681) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9258] GR681 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR681 GENE was detected is described hereinabove with

reference to Figs. 6-15.

[9259] GR681 GENE encodes GR681 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9260] GR681 PRECURSOR RNA folds spatially, forming GR681 FOLDED PRECURSOR RNA . It is appreciated that GR681 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR681 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9261] GR681 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM107 PRECURSOR and GAM264 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9262] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM107 RNA and GAM264 RNA respectively, each of which GAM RNAs

corresponding to GAM RNA of Fig. 8.

[9263] GAM107 RNA binds complimentarily to a target binding site located in an untranslated region of GAM107 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 107A, thereby inhibiting translation of GAM107 TARGET RNA into GAM107 TARGET PROTEIN, both of Fig. 107A.

[9264] GAM264 RNA binds complimentarily to a target binding site located in an untranslated region of GAM264 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 264A, thereby inhibiting translation of GAM264 TARGET RNA into GAM264 TARGET PROTEIN, both of Fig. 264A.

[9265] It is appreciated that specific functions, and accordingly utilities, of GR681 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR681 GENE: GAM107 TARGET PROTEIN and GAM264 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 107D and 264D

[9266] Reference is now made to Fig. 682, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 682(GR682) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9267] GR682 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR682 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9268] GR682 GENE encodes GR682 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9269] GR682 PRECURSOR RNA folds spatially, forming GR682 FOLDED PRECURSOR RNA . It is appreciated that GR682 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR682 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well

known in the art.

[9270] GR682 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM431 PRECURSOR and GAM532 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9271] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM431 RNA and GAM532 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9272] GAM431 RNA binds complimentarily to a target binding site located in an untranslated region of GAM431 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 431A, thereby inhibiting translation of GAM431 TARGET RNA into GAM431 TARGET PROTEIN, both of Fig. 431A.

[9273] GAM532 RNA binds complimentarily to a target binding site located in an untranslated region of GAM532 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 532A, thereby inhibiting translation of GAM532 TARGET RNA into GAM532 TARGET PROTEIN, both of Fig. 532A.

[9274] It is appreciated that specific functions, and accordingly utilities, of GR682 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR682 GENE: GAM431 TARGET PROTEIN and GAM532 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 431D and 532D

[9275] Reference is now made to Fig. 683, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 683(GR683) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9276] GR683 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR683 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9277] GR683 GENE encodes GR683 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9278] GR683 PRECURSOR RNA folds spatially, forming GR683 FOLDED PRECURSOR RNA . It is appreciated that GR683 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR683 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9279] GR683 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM332 PRECURSOR and GAM432 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9280] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM332 RNA and GAM432 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9281] GAM332 RNA binds complimentarily to a target binding site located in an untranslated region of GAM332 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 332A, thereby inhibiting translation of GAM332 TARGET RNA into GAM332 TARGET PROTEIN, both of Fig. 332A.

[9282] GAM432 RNA binds complimentarily to a target binding site located in an untranslated region of GAM432 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 432A, thereby inhibiting translation of GAM432 TARGET RNA into GAM432 TARGET PROTEIN, both of Fig. 432A.

[9283] It is appreciated that specific functions, and accordingly utilities, of GR683 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR683 GENE: GAM332 TARGET PROTEIN and GAM432 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 332D and 432D

[9284] Reference is now made to Fig. 684, which is a simplified

diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 684(GR684) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9285] GR684 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR684 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9286] GR684 GENE encodes GR684 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9287] GR684 PRECURSOR RNA folds spatially, forming GR684 FOLDED PRECURSOR RNA . It is appreciated that GR684 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR684 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9288] GR684 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM352 PRECURSOR and GAM488 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9289] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM352 RNA and GAM488 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9290] GAM352 RNA binds complimentarily to a target binding site located in an untranslated region of GAM352 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 352A, thereby inhibiting translation of GAM352 TARGET RNA into GAM352 TARGET PROTEIN, both of Fig. 352A.

[9291] GAM488 RNA binds complimentarily to a target binding site located in an untranslated region of GAM488 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 488A, thereby inhibiting transla-

tion of GAM488 TARGET RNA into GAM488 TARGET PROTEIN, both of Fig. 488A.

[9292] It is appreciated that specific functions, and accordingly utilities, of GR684 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR684 GENE: GAM352 TARGET PROTEIN and GAM488 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 352D and 488D

[9293] Reference is now made to Fig. 685, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 685(GR685) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9294] GR685 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR685 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9295] GR685 GENE encodes GR685 PRECURSOR RNA, an RNA

molecule, typically several hundred nucleotides long.

[9296] GR685 PRECURSOR RNA folds spatially, forming GR685 FOLDED PRECURSOR RNA . It is appreciated that GR685 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR685 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9297] GR685 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM310 PRECURSOR and GAM507 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9298] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM310 RNA and GAM507 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9299] GAM310 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM310 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 310A, thereby inhibiting translation of GAM310 TARGET RNA into GAM310 TARGET PROTEIN, both of Fig. 310A.

[9300] GAM507 RNA binds complimentarily to a target binding site located in an untranslated region of GAM507 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 507A, thereby inhibiting translation of GAM507 TARGET RNA into GAM507 TARGET PROTEIN, both of Fig. 507A.

[9301] It is appreciated that specific functions, and accordingly utilities, of GR685 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR685 GENE: GAM310 TARGET PROTEIN and GAM507 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 310D and 507D

[9302] Reference is now made to Fig. 686, which is a simplified diagram describing a novel bioinformatically detected

regulatory gene, referred to here as Genomic Record 686(GR686) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9303] GR686 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR686 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9304] GR686 GENE encodes GR686 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9305] GR686 PRECURSOR RNA folds spatially, forming GR686 FOLDED PRECURSOR RNA . It is appreciated that GR686 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR686 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9306] GR686 FOLDED PRECURSOR RNA is naturally processed by

cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM171 PRECURSOR, GAM347 PRECURSOR and GAM457 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9307] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM171 RNA, GAM347 RNA and GAM457 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9308] GAM171 RNA binds complimentarily to a target binding site located in an untranslated region of GAM171 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 171A, thereby inhibiting translation of GAM171 TARGET RNA into GAM171 TARGET PROTEIN, both of Fig. 171A.

[9309] GAM347 RNA binds complimentarily to a target binding site located in an untranslated region of GAM347 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 347A, thereby inhibiting translation of GAM347 TARGET RNA into GAM347 TARGET PRO-

TEIN, both of Fig. 347A.

[9310] GAM457 RNA binds complimentarily to a target binding site located in an untranslated region of GAM457 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 457A, thereby inhibiting translation of GAM457 TARGET RNA into GAM457 TARGET PROTEIN, both of Fig. 457A.

[9311] It is appreciated that specific functions, and accordingly utilities, of GR686 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR686 GENE: GAM171 TARGET PROTEIN, GAM347 TARGET PROTEIN and GAM457 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 171D, 347D and 457D

[9312] Reference is now made to Fig. 687, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 687(GR687) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is

known in the art.

[9313] GR687 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR687 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9314] GR687 GENE encodes GR687 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9315] GR687 PRECURSOR RNA folds spatially, forming GR687 FOLDED PRECURSOR RNA . It is appreciated that GR687 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR687 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9316] GR687 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM96 PRECURSOR and GAM277 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9317] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM96 RNA and GAM277 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9318] GAM96 RNA binds complimentarily to a target binding site located in an untranslated region of GAM96 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 96A, thereby inhibiting translation of GAM96 TARGET RNA into GAM96 TARGET PROTEIN, both of Fig. 96A.

[9319] GAM277 RNA binds complimentarily to a target binding site located in an untranslated region of GAM277 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 277A, thereby inhibiting translation of GAM277 TARGET RNA into GAM277 TARGET PROTEIN, both of Fig. 277A.

[9320] It is appreciated that specific functions, and accordingly utilities, of GR687 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster

of GR687 GENE: GAM96 TARGET PROTEIN and GAM277 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 96D and 277D

[9321] Reference is now made to Fig. 688, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 688(GR688) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9322] GR688 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR688 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9323] GR688 GENE encodes GR688 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9324] GR688 PRECURSOR RNA folds spatially, forming GR688 FOLDED PRECURSOR RNA . It is appreciated that GR688 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence

of GR688 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9325] GR688 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM86 PRECURSOR and GAM202 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9326] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM86 RNA and GAM202 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9327] GAM86 RNA binds complimentarily to a target binding site located in an untranslated region of GAM86 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 86A, thereby inhibiting translation of GAM86 TARGET RNA into GAM86 TARGET PROTEIN, both of Fig. 86A.

[9328] GAM202 RNA binds complimentarily to a target binding site located in an untranslated region of GAM202 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 202A, thereby inhibiting translation of GAM202 TARGET RNA into GAM202 TARGET PROTEIN, both of Fig. 202A.

[9329] It is appreciated that specific functions, and accordingly utilities, of GR688 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR688 GENE: GAM86 TARGET PROTEIN and GAM202 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 86D and 202D

[9330] Reference is now made to Fig. 689, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 689(GR689) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9331] GR689 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR689 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9332] GR689 GENE encodes GR689 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9333] GR689 PRECURSOR RNA folds spatially, forming GR689 FOLDED PRECURSOR RNA . It is appreciated that GR689 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR689 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9334] GR689 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM29 PRECURSOR and GAM180 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9335] The above mentioned GAM precursor RNAs are diced by

DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM29 RNA and GAM180 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9336] GAM29 RNA binds complimentarily to a target binding site located in an untranslated region of GAM29 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 29A, thereby inhibiting translation of GAM29 TARGET RNA into GAM29 TARGET PROTEIN, both of Fig. 29A.

[9337] GAM180 RNA binds complimentarily to a target binding site located in an untranslated region of GAM180 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 180A, thereby inhibiting translation of GAM180 TARGET RNA into GAM180 TARGET PROTEIN, both of Fig. 180A.

[9338] It is appreciated that specific functions, and accordingly utilities, of GR689 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR689 GENE: GAM29 TARGET PROTEIN and GAM180

TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 29D and 180D

[9339] Reference is now made to Fig. 690, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 690(GR690) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9340] GR690 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR690 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9341] GR690 GENE encodes GR690 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9342] GR690 PRECURSOR RNA folds spatially, forming GR690 FOLDED PRECURSOR RNA . It is appreciated that GR690 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR690 PRECURSOR RNA comprises a plurality of seg-

ments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9343] GR690 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM47 PRECURSOR and GAM430 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9344] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM47 RNA and GAM430 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9345] GAM47 RNA binds complimentarily to a target binding site located in an untranslated region of GAM47 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 47A, thereby inhibiting translation of GAM47 TARGET RNA into GAM47 TARGET PROTEIN, both of Fig. 47A.

[9346] GAM430 RNA binds complimentarily to a target binding

site located in an untranslated region of GAM430 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 430A, thereby inhibiting translation of GAM430 TARGET RNA into GAM430 TARGET PROTEIN, both of Fig. 430A.

[9347] It is appreciated that specific functions, and accordingly utilities, of GR690 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR690 GENE: GAM47 TARGET PROTEIN and GAM430 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 47D and 430D

[9348] Reference is now made to Fig. 691, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 691(GR691) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9349] GR691 GENE is a novel bioinformatically detected regula-

tory, non protein coding, RNA gene. The method by which GR691 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9350] GR691 GENE encodes GR691 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9351] GR691 PRECURSOR RNA folds spatially, forming GR691 FOLDED PRECURSOR RNA . It is appreciated that GR691 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR691 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9352] GR691 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM281 PRECURSOR and GAM517 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9353] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA

segments of about 22 nucleotides in length, GAM281 RNA and GAM517 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9354] GAM281 RNA binds complimentarily to a target binding site located in an untranslated region of GAM281 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 281A, thereby inhibiting translation of GAM281 TARGET RNA into GAM281 TARGET PROTEIN, both of Fig. 281A.

[9355] GAM517 RNA binds complimentarily to a target binding site located in an untranslated region of GAM517 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 517A, thereby inhibiting translation of GAM517 TARGET RNA into GAM517 TARGET PROTEIN, both of Fig. 517A.

[9356] It is appreciated that specific functions, and accordingly utilities, of GR691 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR691 GENE: GAM281 TARGET PROTEIN and GAM517 TARGET PROTEIN. The function of these target genes is

elaborated hereinabove with reference to Figs. 281D and 517D

[9357] Reference is now made to Fig. 692, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 692(GR692) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9358] GR692 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR692 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9359] GR692 GENE encodes GR692 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9360] GR692 PRECURSOR RNA folds spatially, forming GR692 FOLDED PRECURSOR RNA . It is appreciated that GR692 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR692 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nu-

cleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9361] GR692 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM98 PRECURSOR and GAM455 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9362] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM98 RNA and GAM455 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9363] GAM98 RNA binds complimentarily to a target binding site located in an untranslated region of GAM98 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 98A, thereby inhibiting translation of GAM98 TARGET RNA into GAM98 TARGET PROTEIN, both of Fig. 98A.

[9364] GAM455 RNA binds complimentarily to a target binding site located in an untranslated region of GAM455 TARGET

RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 455A, thereby inhibiting translation of GAM455 TARGET RNA into GAM455 TARGET PROTEIN, both of Fig. 455A.

[9365] It is appreciated that specific functions, and accordingly utilities, of GR692 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR692 GENE: GAM98 TARGET PROTEIN and GAM455 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 98D and 455D

[9366] Reference is now made to Fig. 693, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 693(GR693) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9367] GR693 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which

GR693 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9368] GR693 GENE encodes GR693 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9369] GR693 PRECURSOR RNA folds spatially, forming GR693 FOLDED PRECURSOR RNA . It is appreciated that GR693 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR693 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9370] GR693 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 3 separate GAM precursor RNAs, GAM74 PRECURSOR, GAM200 PRECURSOR and GAM243 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9371] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM74 RNA,

GAM200 RNA and GAM243 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9372] GAM74 RNA binds complimentarily to a target binding site located in an untranslated region of GAM74 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 74A, thereby inhibiting translation of GAM74 TARGET RNA into GAM74 TARGET PROTEIN, both of Fig. 74A.

[9373] GAM200 RNA binds complimentarily to a target binding site located in an untranslated region of GAM200 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 200A, thereby inhibiting translation of GAM200 TARGET RNA into GAM200 TARGET PROTEIN, both of Fig. 200A.

[9374] GAM243 RNA binds complimentarily to a target binding site located in an untranslated region of GAM243 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 243A, thereby inhibiting translation of GAM243 TARGET RNA into GAM243 TARGET PROTEIN, both of Fig. 243A.

[9375] It is appreciated that specific functions, and accordingly utilities, of GR693 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR693 GENE: GAM74 TARGET PROTEIN, GAM200 TARGET PROTEIN and GAM243 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 74D, 200D and 243D

[9376] Reference is now made to Fig. 694, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 694(GR694) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9377] GR694 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR694 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9378] GR694 GENE encodes GR694 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9379] GR694 PRECURSOR RNA folds spatially, forming GR694

FOLDED PRECURSOR RNA . It is appreciated that GR694 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR694 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9380] GR694 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM129 PRECURSOR and GAM154 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9381] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM129 RNA and GAM154 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9382] GAM129 RNA binds complimentarily to a target binding site located in an untranslated region of GAM129 TARGET RNA, which target binding site corresponds to a target

binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 129A, thereby inhibiting translation of GAM129 TARGET RNA into GAM129 TARGET PROTEIN, both of Fig. 129A.

[9383] GAM154 RNA binds complimentarily to a target binding site located in an untranslated region of GAM154 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 154A, thereby inhibiting translation of GAM154 TARGET RNA into GAM154 TARGET PROTEIN, both of Fig. 154A.

[9384] It is appreciated that specific functions, and accordingly utilities, of GR694 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR694 GENE: GAM129 TARGET PROTEIN and GAM154 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 129D and 154D

[9385] Reference is now made to Fig. 695, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 695(GR695) gene, which encodes an operon-like cluster

of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9386] GR695 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR695 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9387] GR695 GENE encodes GR695 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9388] GR695 PRECURSOR RNA folds spatially, forming GR695 FOLDED PRECURSOR RNA . It is appreciated that GR695 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR695 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9389] GR695 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM336 PRECURSOR and GAM549 PRE-

CURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9390] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM336 RNA and GAM549 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9391] GAM336 RNA binds complimentarily to a target binding site located in an untranslated region of GAM336 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 336A, thereby inhibiting translation of GAM336 TARGET RNA into GAM336 TARGET PROTEIN, both of Fig. 336A.

[9392] GAM549 RNA binds complimentarily to a target binding site located in an untranslated region of GAM549 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 549A, thereby inhibiting translation of GAM549 TARGET RNA into GAM549 TARGET PROTEIN, both of Fig. 549A.

[9393] It is appreciated that specific functions, and accordingly

utilities, of GR695 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR695 GENE: GAM336 TARGET PROTEIN and GAM549 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 336D and 549D

[9394] Reference is now made to Fig. 696, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 696(GR696) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9395] GR696 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR696 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9396] GR696 GENE encodes GR696 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9397] GR696 PRECURSOR RNA folds spatially, forming GR696 FOLDED PRECURSOR RNA . It is appreciated that GR696

FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR696 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9398] GR696 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM426 PRECURSOR and GAM496 PRECURSOR, each of which GAM precursor RNAs being a hairpin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9399] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM426 RNA and GAM496 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9400] GAM426 RNA binds complimentarily to a target binding site located in an untranslated region of GAM426 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or

BINDING SITE III of Fig. 426A, thereby inhibiting translation of GAM426 TARGET RNA into GAM426 TARGET PROTEIN, both of Fig. 426A.

[9401] GAM496 RNA binds complimentarily to a target binding site located in an untranslated region of GAM496 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 496A, thereby inhibiting translation of GAM496 TARGET RNA into GAM496 TARGET PROTEIN, both of Fig. 496A.

[9402] It is appreciated that specific functions, and accordingly utilities, of GR696 GENE correlate with, and may be deduced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR696 GENE: GAM426 TARGET PROTEIN and GAM496 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 426D and 496D

[9403] Reference is now made to Fig. 697, which is a simplified diagram describing a novel bioinformatically detected regulatory gene, referred to here as Genomic Record 697(GR697) gene, which encodes an operon-like cluster of novel micro RNA-like genes, each of which in turn

modulates expression of at least one target gene, the function and utility of which at least one target gene is known in the art.

[9404] GR697 GENE is a novel bioinformatically detected regulatory, non protein coding, RNA gene. The method by which GR697 GENE was detected is described hereinabove with reference to Figs. 6-15.

[9405] GR697 GENE encodes GR697 PRECURSOR RNA, an RNA molecule, typically several hundred nucleotides long.

[9406] GR697 PRECURSOR RNA folds spatially, forming GR697 FOLDED PRECURSOR RNA . It is appreciated that GR697 FOLDED PRECURSOR RNA comprises a plurality of what is known in the art as hairpin structures. These hairpin structures are due to the fact that the nucleotide sequence of GR697 PRECURSOR RNA comprises a plurality of segments, the first half of each such segment having a nucleotide sequence which is at least a partial inversed-reversed sequence of the second half thereof, as is well known in the art.

[9407] GR697 FOLDED PRECURSOR RNA is naturally processed by cellular enzymatic activity into at least 2 separate GAM precursor RNAs, GAM201 PRECURSOR and GAM325 PRECURSOR, each of which GAM precursor RNAs being a hair-

pin shaped RNA segment, corresponding to GAM PRECURSOR RNA of Fig. 8.

[9408] The above mentioned GAM precursor RNAs are diced by DICER COMPLEX of Fig. 8, yielding respective short RNA segments of about 22 nucleotides in length, GAM201 RNA and GAM325 RNA respectively, each of which GAM RNAs corresponding to GAM RNA of Fig. 8.

[9409] GAM201 RNA binds complimentarily to a target binding site located in an untranslated region of GAM201 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 201A, thereby inhibiting translation of GAM201 TARGET RNA into GAM201 TARGET PROTEIN, both of Fig. 201A.

[9410] GAM325 RNA binds complimentarily to a target binding site located in an untranslated region of GAM325 TARGET RNA, which target binding site corresponds to a target binding site such as BINDING SITE I, BINDING SITE II or BINDING SITE III of Fig. 325A, thereby inhibiting translation of GAM325 TARGET RNA into GAM325 TARGET PROTEIN, both of Fig. 325A.

[9411] It is appreciated that specific functions, and accordingly utilities, of GR697 GENE correlate with, and may be de-

duced from, the identity of the target genes, which are inhibited by GAM RNAs comprised in the operon-like cluster of GR697 GENE: GAM201 TARGET PROTEIN and GAM325 TARGET PROTEIN. The function of these target genes is elaborated hereinabove with reference to Figs. 201D and 325D
